Evidence that societal goals and cultural values influence the focus of creative endeavor was put forward by [Razik \(1967\)](#) who argued that economic need and the political situation have tended to influence assumptions about creativity. He pointed out that in the United States even though the Progressive Education Movement, which focused attention on the creative qualities of children, was widespread as early as the 1930s, it was only after World War II in the presence of the Russian threat that creativity could not be left to the chance occurrence of the genius. He observed that, when the need for creative individuals was great, people began to entertain the possibility that perhaps anyone could be creative, and that creativity was amenable to education. [Cropley \(2004\)](#) described how in the United States, the National Defense Education Act adopted a concept of creativity which went beyond its earlier aesthetic definition, to one in which creativity was seen as a key factor in society’s prosperity and survival, thus launching the age of social creativity.

While there are some significant differences between East and West in terms of creativity and culture, the situation is really more complex than this. For example, [Kapur et al., \(1997\)](#) drew attention to the similarities between Indian and Western scientists. However, [Hussain \(2004\)](#) observed that, whereas the West relies on a scientific approach of hypothesis-building and the search for evidence, the traditional Eastern system places great emphasis on building a solid foundation and then building up basic knowledge step by step. But he maintained that the downside of this approach is an overemphasis on the foundations and rote learning—something which he suggested has robbed people of the initiative to make bold hypotheses about new situations and new problems. Another distinctive trait of Eastern culture he identified is humility in learning.

Hussain argued for the importance of understanding how people see creativity in order to help them to improve, and to do this it is important to understand the traditional basis for their creativity. He pointed out that Eastern philosophies like Buddhism and Taoism suggest that there is a need to loosen control and let the mind be free, because as soon as a person tries to create, “to do,” they start controlling. Instead of forcing it, they need to give it a chance to “come,” although he believes that this does not work for everyone.

In Confucianist-influenced societies, such as China, Taiwan, Singapore, Malaysia, and to some extent Japan, the teacher is seen as the master of knowledge who must be respected, and challenging those views can be seen as inappropriate. According to Sharma [Sen and Sharma \(2004\)](#), in India, school children are expected to comply with authority and follow their teachers’ (gurus’) instructions. The unwillingness to question the authority of teachers has emerged in a number of countries, although of course this is not universal within or across cultures.

Other researchers have drawn attention to features of Asian cultures which can foster creativity, including an emphasis on collectivism which can encourage working together for incremental innovations. They also highlighted the fact that Asian cultures often encourage long-term goal setting and perseverance which would be beneficial to creativity.

Hussain highlighted the incredible creativity and inventiveness of Chinese society as well as the outstanding works of great thinkers like Confucius. But despite all these achievements, he suggested that there have been no similar breakthroughs in the last 1000 years. He ascribed this change to a lengthy period of feudalism and the rigid and deeply entrenched Imperial Examination System. He contrasted this with a much shorter period of feudalism in Europe followed by the Renaissance and later the Industrial Revolution. Hussain concluded that the historical conditions in the West over the past few centuries have been very favorable to creativity and inventiveness, whereas in the East the historical conditions have been less favorable. But, he argued, the Western emphasis on individual achievement over collective effort also has its disadvantages: although it can spur people on to greater accomplishments, it results in self-centered individualism which indirectly affects creativity.

One of the ways researchers have tried to make sense of all the contrasting features of different cultures is by adopting categories such as those featured in [Hofstede’s 1991](#) study of IBM’s international employees:

- Individualism—collectivism
- Power distance relationship
- Masculinity—femininity
- Uncertainty avoidance—uncertainty acceptance

According to [Lubart \(2010\)](#), in studies of national inventiveness and innovation, it appears that societies which feature individualism, low power distance, and low levels of uncertainty avoidance are more likely to be inventive and innovative. However, countries with high levels of individualism may struggle with idea implementation, as this stage often requires a team effort.

Obviously the detailed picture is more complex, and individual cultures cannot be classed as simply as Hofstede’s criteria might suggest. Within every culture, there will be pockets of creativity as well as sections of society who resist creativity. For example, citing Lau, Hui & Ng, [Lubart \(2010\)](#) explained that Chinese culture is complex and cannot be reduced to being simply “collectivist.” Indeed [Raina \(2004\)](#) pointed out that: “creative thought in the Oriental traditions cannot be treated as a single, undifferentiated entity”. And he articulated what many literature reviews strongly suggest, that theories of creativity derive from cultures’ creation myths. The word derive seems important here since (if he is interpreted correctly) he was referring to the religious basis of creativity in each culture, whether Indian, Greek, or Judaic, for example. Hussain also emphasized how Islam laid the cultural and scientific foundations of the modern world.

In addition, Raina criticized the “narrow ethnocentric” boundaries of most creativity research and argued instead for a “garland making perspective on creativity and cultural diversity”—one which allows a diversity of approaches to flourish and which recognizes the complexity involved:

Be like a garland maker, O king: not like a charcoal burner.

Mahabharata XII. 72 20 in [Raina, 2004](#), p. 27

As Raina explained, this famous metaphorical statement contrasts the creation of a garland of many flowers and colors against a charcoal burner burning all kinds of diverse wood into homogeneous dead matter. Given the increasing ease with which information and ideas can be shared globally, it seems relevant to ask to what extent East/West comparisons will be useful in the future? Hopefully the world is not moving toward a state of “homogeneous dead matter.”

Reviewing Cross-cultural Research Literature

When undertaking cross-cultural research, the many variables discussed above clearly need to be taken into account, but even more care needs to be taken when *reviewing* cross-cultural research—ensuring that one compares like with like or that any differences are made clear. Another key consideration concerns clarity around *the criteria employed by reviewers* for the inclusion of studies in the review. Such clarity is evident in a highly comprehensive review of East/West cultural differences in creativity and innovation by [Xie and Piak \(2018\)](#) in which they decided to include both studies of “creativity” which they see as idea generation and “innovation” which they see as including “creativity (i.e., generating ideas) ... as part of the innovation process.” Not everyone would define

“creativity” so narrowly nor would they necessarily define “innovation” in this way but importantly they have made their criteria clear as well as providing information on how these and other terms have been defined in the research reports they review. Their review clearly illustrates the complexity involved in such a task. That they identified gaps in research which could usefully be addressed in the future is an added bonus.

Prior to this, [Simonton and Ting \(2010\)](#) published a useful review of research into creativity in Eastern and Western civilizations in which historiometrics had been employed as the methodology. They too make clear the complexity involved in such comparative research while drawing attention to the unique potential of this methodology. Clearly any historical cross-cultural review of creative achievement needs to take account of the extent to which different sectors of the population had the freedom or opportunity to express their creativity. In the United Kingdom, for instance, historically women faced restrictions on what they could do (and such restrictions still apply in a number of countries today) which has meant that they tend to be underrepresented in historical accounts of creative achievement. This is yet another issue of which cross-cultural researchers need to be mindful.

Creativity Researchers' Views About Their Own Countries

[Paletz and Peng \(2008\)](#) reached an important conclusion, which is to understand that:

"Implicit theories of creativity may go beyond stereotypes about East-West differences ... the nature of creativity is multifaceted: if we view it through the eyes of people across the world, we can better understand which aspects are universal and which are culture specific." (p. 299)

The views expressed below are the considered opinions of eminent creativity researchers selected for their knowledge of the creativity field in their own countries. They were asked:

- What factors do you think especially support creativity in your country today?
- What factors do you think inhibit it?
- Is there anything else you would like to say about creativity in your country?

Australia—Michelle Evans

Australia is a creative nation. Our innovative spirit can be traced back well before the colonial invasion in 1788 by the British. The place-based Indigenous knowledges connected to all corners of the breadth of Australia are embodied in creativity and cultural practices of Australian Indigenous people. These Indigenous knowledges are derived from mutual relationships with the land, seasons, flora, and fauna. Indigenous cultural and creative expressions through dance, song, music, language, and visual artistry continue to be practised in various parts of Australia. From traditional cultural expressions to contemporary artistic forms, Australian creatives draw upon the unique nature of our island home.

Indigenous innovations like the boomerang, that served as an excellent tool for many uses for thousands of years, was the inspiration of the famous patent registered by Ngarrindjeri creator David Unaipon. His ideas about perpetual motion led him to register 10 patents including the modern mechanical sheep shears. These ideas have been instrumental, including drawings designing a helicopter on the principles of the boomerang, which we now know served as the base idea leading to the design of modern-day drones. Many Indigenous Australian creatives are using drone technology today—such as the cultural entrepreneurial company, Indigital, who survey the country from the air, creating 4d maps. These maps are layered with content from traditional elders for instance, in order to create rich visual and textual environments in augmented reality.

Creativity is embraced across sectors: from education to health, from the arts to business, we can see how critical the pivotal role of creativity is in the rising knowledge economy. In the knowledge economies, where ideas and creativity represent the primary materials of the system, high levels of education are the building blocks for expertise and specialization. Australia ranks in the top 10 of tertiary educated populations in the world as well as in the top 10 for global patent filings. This traditional measure of demonstrated creativity (patents) indicates that Australia clearly supports innovation and creativity. Structural inequality inhibits access for individuals and groups to creative education, funding opportunities, and expression opportunities, as well as the opportunity to learn critical and creative thinking.

China—Hongyi Sun

Chinese people used to be very creative in the ancient days with the four great inventions, i.e., gun powder, the compass, paper, and printing. However, in the past hundred years, there have been very few original inventions from China. This echoes the famous Needham Question. Experts believe that culture is one of the critical influencing factors on creativity. Chinese cultures used to be very tolerant with many different schools of thought (without Buddhism then), for example, in the great four invention period.

Later on, it was dominated by Confucianism for a long time. Its current culture changes in some aspects as well. How current Chinese culture influences its creativity is a timely and important topic to study.

Sun (2009) used the six dimensions of national culture by Hofstede (1991) and the two dimensions by Hall (1989) to study the impact of national culture on innovation. Findings indicated that power distance, individualism, scientific thinking, and precise thinking were positively related to the innovation capability of a nation. China is very weak in equality (large power distance), individualism, precise thinking (quite nonprecise in many aspects), and extremely weak in scientific thinking. The ranking of China in these dimensions reflects a typical Confucian Society. Due to these cultural features Chinese people, especially students, are very shy and have no confidence when dealing with new ideas. Therefore, some dimensions of Confucianism may inhibit creativity in China.

However, there are some elements in Chinese culture that may support creativity. Among others, there is a paradox with regard to intuitive thinking. People normally believe that intuitive thinking should positively support creativity. This really depends on how creativity and innovation are defined. If creativity is defined as the process of generating new ideas, intuitive thinking is really positive. However, looking at the innovation process which starts with a new idea, develops it further into a feasible product (or service) and commercializes it in the market, intuitive thinking is far from enough and in fact damages the downstream stages. Chinese people and the education system are especially weak in systematic and process-oriented thinking. Even with good ideas, the ideas will lead to nothing if this involves just playing with the ideas. Therefore, a systematic and process-oriented tool like the PIPE model (Sun, 2012) is needed in Chinese creativity education and training.

The Chinese government strongly supports creativity and innovation. All its policies aim at building an innovation-based country. Chinese companies and universities are all encouraged to move toward innovation. However, the top-down push approach may backfire on the operational level. Creativity has to be bottom-up at people's free will.

Finally, there is a very practical method in China for creativity training. Many empirical studies report the positive impact of meditation on creativity (see for instance Alexander et al., 1991; Seeman et al., 1972; Alexander and Langer, 1990). China has a long history of practising meditation by Buddhism and Taoism as well as Confucianism. Surprisingly, meditation is more popular in the West than in China now. From famous entrepreneurs to ordinary engineers of Google and Microsoft, meditation is practiced. These companies even provide meditation rooms for their employees. Chinese meditation in Buddhism Zen and Taoism Taiji meditation have been influencing China, Japan, Korea, Singapore, and Vietnam for hundreds of years. It has the potential to be developed into a modern creativity training method in China.

Germany—Luzie Semmler and Verena Pietzner

Semmler and Pietzner's study dealing with teachers' and student teachers' views on creativity revealed that German teachers and student teachers who participated in the study have a positive attitude toward creativity and realize the importance of supporting creative abilities in pupils. This is encouraging as children's creativity and creative abilities need to be supported as early as possible. Indeed, schools are important institutions in the context of supporting creativity. This attitude as well as the openness and the will to deal with creativity by themselves increased not only the respondents' creativity but also the creativity of pupils in their classes.

One important point is that within the core curriculum published by the KMK, teachers have freedom to include special activities. It is more open than in other countries, the group of subject teachers within a school have the responsibility to design a school curriculum out of the core curriculum. There, they can include topics that foster creativity, especially by choosing methods which encourage respect. Usually, teaching methods that foster creativity are widely known but more as methods to foster cooperative learning or to make teaching more open. Teachers are not generally aware that these methods also foster creativity.

Another factor involved in supporting creativity in Germany is the possibility of expressing one's own way of life and individuality. Germany's economy has grown rapidly over the past few years, and all doors are open to young adults for experimenting and realizing their ideas. Furthermore, the increasing globalization and digitization, not only in Germany, but all over the world, offer new possibilities to be creative and to exchange with others. New digital media also opens up new possibilities in school to support creativity, but the new media's potential is still not reached.

Dealing with creativity in young children is an important aspect in the development of creativity. Creativity is not a talent; it is an ability that can be learned and developed by every person. Although creativity is important in every area of life, and, thus, in every school subject, in German schools, creativity remains in artistic and musical subjects. Especially in today's digitized times, economy and industry depend more and more on innovative and creative workers, because ideas are developed and spread via the Internet at incredible speed. To stand out in international competition, the German economy and industry need innovations developed in short time intervals. Creativity, therefore, needs to be a requirement for school graduates, and it should be integrated and facilitated in every school subject. This includes stimulating divergent thinking processes, supporting self-initiated learning, and allowing pupils to make and correct mistakes. These aspects are implemented in German schools only rarely. Therefore, the current classroom situation in German schools is not intended to support creativity.

Teachers also need time to be creative. Teachers in Germany struggle with many challenging tasks including children with disabilities in regular classes or the turnover at the gymnasium (switching from 8 years to 9 years). If teachers feel more and more overloaded, they do not have the time to think about creativity and/or being creative.

India—Rehka Sharma Sen and Neerja Sharma

Creativity has been valued in its diverse dimensions since ancient times in Indian society. Presently, there is a multiplicity of implicit theories of creativity extant in Indian culture, and these reveal continuity with traditional Indian philosophical thought as well as the integration of a Western world view.

Creativity, in Indian philosophical texts, is much more than either the process of creation or the novelty of the product. It is seen as a faculty, distinct from the intellect, and is referred to as *pratibha* or intuitive creative power. The faculty of *pratibha* is what enables the creator to create and communicate one's experience, and it is this faculty which enables the aesthete to grasp, experience, and understand the meaning in the creation. Creativity, or *pratibha*, lies in the communion between the creator and the aesthete though they may be separated in space and time. Creativity originates with the bliss of the creation in the artist's mind and is completed in the aesthete's heart, which fills with the same kind of bliss on experiencing the creation (Deshpande, 1989).

In daily life, it is the *agency of the self* in the process, of creation, the involvement and investment of the self in the task being done, rather than merely bringing a product into being, that is invoked in considering the self as having been creative. Multiple conceptions of creativity exist in this self-based construal, depending upon which aspect of the self is considered salient in evaluating whether or not one has been creative. Both the "meaning context" of creativity (Stark, 1965) and the "novelty context" of creativity (Nickerson, 1999) have currency in people's thinking (Sharma Sen and Sharma, 2011).

- For some, the emotional self is of salience in order to evaluate the self as creative. These individuals experience agency and involvement when they *invest themselves emotionally* in the task. Creativity is described with reference to emotions, feelings, and the subjective state of the person when involved in a task, irrespective of ownership of the idea as one's own. Thus reproducing art is seen as a creative act when it is not simply a mechanical act of copying. "Newness of thinking" or creation of something "new," "different" or "unusual," "neat," or "attractive" is of no special significance and, when it happens, is epiphenomenal.
- For some, the cognitive self is of salience, and they describe creativity with reference to the thinking and cognitive processes that accompany the act of creation. Actions, products, and ideas that are borne out of the person's *own* thinking, which are not routine, not mechanically done out of habit, where the outcome or the solution is not predetermined or previously known to the person, are described as creative. Problem-solving is seen to be as much a creative act as creation of a novel product.
 - Some assess "novelty" and "originality" of thought in a comparative sense, with respect to others.
 - Some assess "novelty," "difference," "originality," and "uniqueness" of thought with respect to one's own self.
 - Some do not stress comparison in any sense and focus on self-expression rather than being unconventional or new. "Unique" is used to describe creativity not in the comparative or quantitative sense of "rarity"; but as "uniqueness" of one's style, one's individuality as one expresses oneself through the creation.
 - Many describe creativity as the act of learning, especially in the context of education. The connotation of "newness" here is "learning new things or skills" or "what one did not know before" which is different from the connotation of "newness" as "person's new ideas." Creativity is seen to lie in the process of appropriating knowledge through one's active agency, in reconstruction and discovery of knowledge by the doer in order to assimilate it to one's self.
- Some invoke the holistic self in defining and experiencing creativity. An action or experience is perceived as creative because of the person's total involvement in it—mental, emotional, and physical. Newness of thinking is epiphenomenal, holding no special significance. Such a view is especially relevant in understanding the creativity of artists involved in creating traditional crafts and those engaged in the traditional performing arts. The element of creativity in the work as "self-expression"/"uniqueness"/"different"/"originality" and the element of recognition of the work as "new"/"novel" are seen as two distinct aspects—the former is seen to lie in the domain of the artist and the second in the domain of the audience. As such, the artists themselves do not strive for "newness"/"novelty"—it happens. Reinterpretation of the traditional is creative because it emanates from the creator's entire being.
- For some, the physical act of creation is the defining feature of creativity—a person is seen to be creative because one is doing something or bringing something into being, into physical existence. Novelty, originality and ownership of thought or emotional involvement are irrelevant.

In terms of teachers' perception of traits which ought to be there in an "ideal child," creativity-relevant traits of the Ideal Pupil Checklist, such as "independent in thinking," "courageous in convictions," "curious," and "persistent," find a place within the top five highly valued traits, and "conformity" (which is seen as a deterrent to creativity) is among the least valued traits (Sharma Sen and Sharma, 2004). However, this positive perception of creativity-relevant traits is not reflected in actual teaching practice in schools. Students and teachers largely perceive "academics" as a domain which is fixed, theoretical, and fact-based, where things have to be understood as they are and written in examination. Academics is seen to require "intelligence" narrowly interpreted as information, memorizing, reproducing, and understanding. Children do not experience a sense of agency in the classroom, which is central to their construal of creativity. Further, school tends to foster a domain-specific view of creativity, as dominantly associated with the arts and crafts (Sharma Sen and Sharma, 2009).

In terms of familial environment for creativity, key features seem to be a strong parental motivation to nurture their child's creativity and a strong internal motivation of the child to persevere in the chosen domain. The availability of cultural capital and deliberate and sustained connection with the field and the domain, positively contribute to the emergence of creativity. A cohesive family environment, where the members share a commonality of goals and purposes and availability of structured support, seems to play a central role in the nurture of creativity and its continued development. The conscious decision of the family to allocate time,

energy, and resources for the nurturance of a child's creativity, seeing it as a priority, seems to be pivotal (Sharma Sen and Sharma, 2013).

Japan—Kenichi Yumino and Tomoki Saito

Japan, in which the rice growing culture has been prospering from ancient times, has “the concept of improvement.” This came from the fact that the harvest increases whenever a farmer deliberately cares—tending the crop with water and manure and taking care of the environment. This concept is inherited up until today and draws “innovation” into study, in industry and in the business world. This brings about a steady stream of big results. For example, 39 Japanese companies were chosen as part of the “100 Top Global Innovators 2017” by Clarivate Analytics, USA. In addition, in order to maintain rural small cities and towns in which the population of elderly people increases so rapidly, people create special products and innovative businesses to attract domestic and overseas sightseers. On the other hand, many organizations have failed to innovate because of a lack of resources, including labor, and because of slow decision-making.

In Japan, the word “creativity” is often used when referring to talent and the works of special people such as a great scientist, writer, architect, painter, or musician. The number of Japanese Nobel Prize winners who are called the greatest scientists increased rapidly in the last 20 years (18 winners). The following reasons for this can be inferred. The number of university students has increased rapidly since the 1960s. Many students studied in American universities or research institutes and discovered themes that connected to the Nobel Prize and, after trial and error, they finally completed these studies. Their dexterity and their ability to think out unusual problem-solving methods may have contributed to their success.

In the 1970s, American culture influenced fields such as fashion, design, painting, photography, and music. People were developing creative works (such as animated cartoons, comics, fashion items, and costume play clothes) based on the concept of “Kawaii: pretty, lovely, cute, little, tiny” that is peculiar to Japanese culture.

One way in which creativity education is carried out is in super science high schools and elementary and junior high schools attached to colleges. Creativity education is also encouraged in high schools and in colleges with engineering sections by holding contests in programming robots and designing solar cars.

A few research projects aim to increase students' creativity through the Science-Technology-Society and Science-Technology-Engineering-Mathematics approaches, and they are obtaining good results. The authors divide “learning” into “Manabi: acquisition” and “Tsukuri: creation.” However, in ordinary schools, most lessons are Manabi and the lessons that step into the Tsukuri domain are rare. The reasons for this are:

- a) Japanese teachers and parents who do not know much about foreign advanced education think that Manabi is “all of learning” and do not demand the education that steps into the domain of creativity.
- b) Pupils learn many subjects shallowly. Therefore, they lack training in thinking deeply.
- c) On the last page of a textbook unit, problems (tasks) are always given instead of allowing students to set problems for themselves. In other words, students are trained in problem-solving but not problem setting.
- d) The utilization of the “period of integrated learning” which aims to build on each pupil's interest is insufficient.

Mexico—Lilian Dabdoub

Mexico is amidst a big transformation, and creativity is a goal of the National Education Plan (2013–18). Nonetheless, as any cultural transformation, it will take time to obtain evidence as to whether the expected changes to the educational system had an impact on children and teachers' way of thinking.

Trying to answer which are the factors that enhance or inhibit creativity in the Mexican culture is a complex task since Mexico is a mosaic built with a wide variety of cultures, socioeconomic levels, and traditions from distinct regions of a country of more than 129 million population. However, I will try to underline some aspects, which I consider, enhance creativity in the Mexican culture.

Creativity, as an original response to solve a problem, is expressed in everyday life within Mexican culture. The factors, which may enhance creativity, depend on the specific socioeconomic context. Interestingly, there is a saying *La creatividad de los mexicanos*—Mexicans are highly creative, since in general, when facing a problem and/or a situation of need, they tend to find ways of solving the need or the problem in spite of the fact that they may not have the right resources for doing so. The lack of resources ignites the spark of Mexican creativity. In the eyes of an expert, perhaps the solutions that a Mexican can implement are not the most orthodox ones, but they solve the need or the emergency.

Mexican society, in general, has shown in different tragic events, such as the earthquake in 1985 or the more recent one in 2018, their resiliency. I found that creativity and resilience relate to each other since creative skills may enhance the capacity of the individual to recover from a traumatic experience and become stronger. In addition, in such circumstances, collective creativity and solidarity are outstanding.

Recently, there have been examples of creativity in the arts, science, robotics, and cinema to mention a few arenas where Mexican creativity has been widely recognized. Cultures are influenced by the stories—the narratives that are repeated and are immersed in

a way of thinking or acting. One narrative immersed in Mexican culture is that the people who have lived in this land were colonized, and, as a colonized and emergent country, there is a perception of inferiority in relation to the conquerors. Nevertheless, one characteristic that could hinder creativity, an inferiority complex explained by authors like Octavio Paz, may turn into a strength due to the willingness of the Mexican people to embrace challenges with courage, finding ways to overcome obstacles with original approaches.

Portugal—Fatima Morais

In Portugal, there is now a stronger presence of academic research about creativity and a consequent expansion of the topic e.g., in conferences, workshops, and teacher training. The need for creative problem-solving skills has become increasingly obvious, particularly in the business world. In addition, there is the development of some private associations, such as the Torrance Center, Portugal, which provide concrete tasks in order to promote creativity—mainly in educational contexts (teacher training and creativity training programs in schools).

Despite this, creativity is not sufficiently addressed and invested in the academic/higher education domain. For example, not enough attention is given to the need to create formal courses or to offer teacher training (teacher training only exists for basic and secondary schools). At university level, creativity is still often a “taboo” and not treated as a serious and scientific topic. The result is that creativity is frequently misunderstood by the general public. Indeed, there is a discrepancy between the explicit goals of creativity promotion in the formal educational system (from preschool up to and including university) and the real investment in schools and teachers. Another barrier is the existence of “classical” myths about creativity, namely the genetic influence, the association with disruptive behaviors, the confusion between creativity, talents and giftedness, and, mainly, its primary association with the arts.

However, globally the changes are positive. There are now more scientific national and international publications about Portuguese research. Recent research has included a production/adaptation of measurement instruments, systematic control in the evaluation of training programs, the relationships with psychological variables (for example, motivation, intelligence), and the creativity of famous women. There are more schools intentionally taking action with regards to pupils’ creativity, and there is a slight increase in reinforcement through private grants and creativity development programs or methodologies in the school context. However, the business and artistic contexts are more explicitly associated with creativity; in the first case (enterprises), a growth of investment in creativity is clearly evident over the last 7 to 10 years.

Romania—Daniela Zaharia

In Romania, creativity is considered to be both an individual characteristic and a social phenomenon. Both these conceptualizations have captured the attention of researchers but mostly of practitioners. Specialists in various fields have developed programs aiming at developing the creative potential of both children and adults.

For example, one of the aims of the national educational system is to develop children’s and young adults’ creativity. Various extracurricular activities are designed for that purpose by educators from both public and private schools. The advantage of private schools (from this point of view) is that classes are composed of fewer children (15–20) as compared with public schools (25–35 children in a class). Consequently, educators have more time to interact with each child and adopt strategies that are aligned with his/her individual characteristics. During the last 10 years, a lot of private organizations have proposed educational activities aimed at developing children’s creativity and their approach was and still is successful, because many parents are interested in such proposals.

While discussing adults’ professional activities, the interest in the employees’ creative potential is high only in some domains (e.g., research and development in IT, marketing, and advertising). In the last 10 years, the phenomenon of outsourcing brought into Romania a lot of companies that provide such services (especially in human resources or client support and service areas of expertise). These companies come with very specific procedures that need to be applied thoroughly and do not encourage creativity.

In the art domain, Romania won important prizes within very prestigious film festivals (Cannes, Berlin) in the past 10 years. This international attention helped these Romanian movies gain prestige and greater interest in the film industry at home.

Creativity is also valued in higher education. Creativity courses are provided in at least four universities. Moreover, there are some empirical studies conducted in this area. For example, there is an international peer-reviewed academic journal entitled *Romanian Journal of Artistic Creativity*. Moreover, a set of scientific papers written by Romanian researchers was published in the *Creativity & Human Development* journal in 2016 on themes such as the relationship between creativity and conflict, creativity and unconscious thought, the impact of music on creativity, and talent promotion in Romania.

One interesting thing about Romanian creativity is how it reveals itself in the way Romanians protest against their political leaders. This specificity was obvious during the communist regime, when most people used to tell “undercover” jokes about Ceausescu and his wife (in those times, such jokes used to lead to very serious consequences if they were reported to the Department of State Security). Since 2017, Romanians have been using wit and humor again in their anticorruption protests.

Spain—Manuela Romo

Creation in Literature and Fine Arts is still very abundant as it has been throughout history. Also the film industry embraces a lot of creativity with filmmakers who are highly recognized and have received awards throughout the world. The same goes for fashion.

In the business world, creativity in Spain is mainly associated with advertising and marketing as well as entrepreneurship which began to be very important as a result of the economic crisis that began in 2008. This caused a lot of unemployment and demanded the development of the creative and innovative skills of individuals or small groups so that they could create new businesses. In startups, it is understood that innovation is the best tool to make a business competitive.

Unfortunately, creativity in the educational field does not receive the consideration it deserves in the training of teachers. In the university sector, topics on creativity are scarce and virtually limited to Advertising and Communication degrees. Some exceptions in other areas, such as Psychology, are due to a particular commitment to incorporate studies about creativity in universities. In general, talent continues to be associated almost exclusively with intelligence.

The truth is that neither schools nor higher education promotes creativity so that the stimulus to creativity in training occurs in isolated cases where isolated teachers use creativity as an educational tool and as a goal of individual development but without it explicitly appearing in the school curriculum. Nor has there been much consideration of innovation in the field of organizations. The public authorities have not devoted large investments to the development of R & D although the situation is beginning to change due the demands of the information society and the globalized world where the generation of new information requires creative thinking. One hopeful sign is the creation of new businesses by young people who apply innovation to their products and services often intuitively, although business schools also incorporate training in innovation and creativity techniques in their programs.

United Kingdom—Marilyn and Caroline Fryer

In many British people's minds, creativity is still primarily associated with the arts and the "creative industries" which are quite narrowly defined. However, in higher education, a significant number of academics across the board take creativity development seriously and ensure that it is included in their courses, research, and other activities. Similarly, it is addressed in staff development in UK organizations, though not always as widely as it could be.

However, government interest in creativity development in school education tends to swing back and forth on a regular pendulum, and this swing appears to coincide with changes of government, with the socialist governments being more in favor of creativity education than the conservative ones. For example, today in England, creativity education no longer has the prominent place it held at the beginning of this millennium when we were working with the then Qualifications & Curriculum Authority to ensure that creativity development was explicitly included in the National Curriculum for England. But there is a little evidence that it may soon be on the agenda again. Despite these pendulum swings, there will always be teachers who recognize the importance of developing creativity and who work hard to do so, regardless of government policy.

The main current problem for schools in the United Kingdom, stemming from a general government austerity policy, is lack of funding which means that essential services have been cut, and this particularly affects provision for children with special needs and the range of subjects offered to pupils—the arts in particular have been badly hit. There are significant teaching and support staff shortages as well as a lack of resources. This lack of investment coupled with the neglect of creativity education in schools would seem short-sighted in view of the significant problems we face locally, nationally, and globally—problems which require creative solutions. The United Kingdom is very much a nation of immigrants which can continue to benefit from cultural diversity (Fryer & Fryer, 2005; Bolingbroke & Fryer, 2009). In 2002, our charity, the Creativity Centre Educational Trust (CCET) ran the country's first *Creativity and Cultural Diversity* international conference to highlight this (Fryer, 2004). Since then CCET has launched an international e-journal, *Creativity & Human Development* (www.creativityjournal.net/) and worked on bringing the research fields of creativity and human development closer together.

Concluding Comment

Many years ago, Torrance (1962) observed that what society values will be championed there. While it is clear from the researchers' accounts above that there is evidence of the championing of creativity, the picture is patchy—not all policy-makers and gate keepers understand the relevance of creativity in human development and behavior and the need for high-quality creativity education and training. Given the complex and challenging problems facing all levels of society, a genuine commitment to expanding understanding of creativity has never been more needed.

Acknowledgments

Marilyn and Caroline Fryer wish to express their sincere thanks to the following distinguished researchers who have given their views on creativity in their own countries:

Michelle Evans
Hongyi Sun

Luzie Semmler
Verena Pietzner
Rehka Sharma Sen

Historical Context

The interactions between many cultures throughout the history of South American countries can help understand the ways creativity is expressed in these nations. The impact of the Incas, who settled in the Andes Mountains of Peru around 1200, was exemplified in their construction of Machu Picchu. This outstanding mountaintop community demonstrated their creative ways of handling architecture, astronomy, agriculture, and ceramic artwork. In Brazil and Paraguay the Tupi-Guarani Indians influenced the dialects and expressions used in these countries today.

The European conquerors were led by Christopher Columbus, who arrived in 1492, and Pedro Alvares Cabral, who arrived in 1500. The Spanish and Portuguese suppressed the Indians' culture through force and by converting them to Catholic religion and symbols. They killed the vast majority of natives, but some Indian Reservations still remain throughout S. America. In Brazil, there is a total of 350 tribes, totaling 0.4% of the population, primarily living in the Amazonas region ([Survival International, 2019](#)).

The interaction of Spanish and Portuguese settlers resulted in many conflicts over land. Finally, this rivalry was solved by the Treaty of Tordesillas, brokered by Pope Julio II in 1506. The division explains today's language difference where Brazil speaks Portuguese, while all the other nations speak Spanish.

Later on, other immigrant groups from Italy, Germany, Dutch, Japan, and China shaped and enriched their cultural expression of creativity. The presence of African slaves, brought by the Spanish and the Portuguese to work in the fields, influenced the ethnical as well the cultural life. Brazil received the largest population of Africans to work in northern states, at the sugar plantations, and in the southeast states to work at gold mines.

The presence, as well the suffering, of these slaves had an enormous impact on Brazil, as unfortunately it was the last country to abolish slavery in 1888. The historical cities in Minas Gerais (e.g., Ouro Preto, Mariana, Tiradentes) demonstrate the Portuguese and Africans' influence on the style of colonial houses and through the artwork presented in the churches, where gold was mixed with wood to represent the Saints and Catholic symbols. The most famous Baroque artist of the 18th century was the Brazilian *Aleijadinho*, insensitively nicknamed little cripple due to the loss of hands and feet caused by leprosy. He sculptured the 12 prophets in their actual size in soapstone, at the Sanctuary Bom Jesus do Matosinhos in Congonhas City. They are dressed in Portuguese robes but with African faces. The African influence upon Brazil is evident in the mixed integration of races. Africans did not influence visual arts, music, dance, food, and religious expression.

Creative Expression in Diverse Domains

The range of creative manifestations in South America is very rich due to the diverse cultures and races who live there. These countries were always open to immigrants.

Visual Arts

South America has produced outstanding creative persons, mostly from the Human and Arts domain. In the domain of Poetry, for instance, there are eminent persons who were known internationally, such as *Jorge Luis Borges*, from Argentina, *Pablo Neruda*, from Chile, and *Oswaldo de Andrade*, from Brazil. In the literature domain, excellence was recognized to *Mario Vargas Llosa*, from Peru,

Gabriel Garcia Marques, from Colombia, and *Jorge Amado*, from Brazil. In the Visual Arts domain also, there are a variety of exceptional painters, such as *Claudio Bravo*, from Chile, *Benito Quinquela Martin*, from Argentina, *Joaquin Torres Garcia*, from Uruguay, *Armando Reveron*, from Venezuela, and *Tarsila do Amaral* from Brazil, who represented their culture from a myriad of colorful perspectives. In February 1922, the “Week of Modern Art” was launched, which had a great impact on the Brazilian visual arts and literature, led by artists and poets (*Di Cavalcanti*, *Oswald de Andrade*, *Mario de Andrade*, *Lygia Clark*) with a movement named “Antropofagia” (anthropophagy), meaning the search for indigenous roots and the primitive spontaneity to express Brazilian creativity, free from European influences.

The economic situations faced by the majority of South American countries resulted in the preference for another type of visual expression, away from art galleries or museums, but open to public in wide spaces. Street art or “neo-graffiti” is considered the primary form of protest in these countries, since the first murals were painted by the Mexican painter Diego Rivera. Nowadays it is legalized and is the most popular means of expressing creativity in urban spaces in Chile, Brazil, Argentina, Nicaragua, Venezuela, Bolivia, Colombia, and Peru, reaching a profusion of outdoors and building facades throughout the cities. In these countries, it is possible to find many “barrios” or city quarters with an abundance of artwork. Several outstanding street artists can be named such as *Inti Castro* (Chile) and the Brazilians *Vik Muniz*, *Gustavo and Otavio Pandolfo* (*OsGemeos—The Twins*), and *Eduardo Kobra*, who painted the world’s largest street mural for the Olympic Games, displayed next to the Museum of Tomorrow in Rio de Janeiro.

Architecture and Design

Focusing on the domain of Architecture, there is the well-known Brazilian architect, *Oscar Niemeyer*, who designed the main buildings of the city of Brasilia, the capital of Brazil, such as the senators’ house, the presidential residence, the main cathedral, and the federal university. The outstanding modern style of Brasilia’s buildings was recognized as *UNESCO World Heritage*, in 1987. Another exceptional creative contribution can be accredited to *Burle Marx*, known as a Brazilian modern nature artist and public urban space designer, who had a great influence on tropic garden design and scenery in the 20th century. His old house, in Rio de Janeiro (Roberto Burle Marx farm), became a famous museum, recognized as holding the one of the best collections of living plants in the world. The *Inhotim Institute*, located in the state of Minas Gerais, is the largest outdoor art center in Latin America, blending sculptures, visual arts, and gardens, in a splendid combination.

Music and Dance

Another typical creative expression from South America is revealed through music and dance, recognized worldwide. One of the best examples of these manifestations is the carnival, considered one of the most popular creative ways of combining religion and culture through music and dance, which is present in many South American countries, but the best known one is in Rio de Janeiro. In Rio, the carnival parade is composed of huge amount of people dressed in different costumes, dancing in the streets or upon electric cars fully decorated, presenting the main themes of each *samba school*. Interested people from all socioeconomic classes engage in training to participate in the samba schools during a whole year, thus indicating this is really a cultural creative expression. Another Brazilian music expression, known internationally as the *bossa nova*, was created by *Antonio Jobim*, *Gilberto Gil*, *João Gilberto*, and *Chico Buarque*, who had some of their songs translated by *Sergio Mendes* in the United States. The influence of the African culture is alive today in other Brazilian music styles, such as *Batuque*, *Axé*, *Forró*, *Pagode*, *Maracatu*, and *Olodum*, which are celebrated all over the year in musical festivities in the northern states.

In the neighboring country, Argentina, the traditional music and dance style is the *Tango*, which originated in the 19th century when Italian immigrants were arriving. The music was combined with the drums brought by the African slaves, portraying a very sensitive and emotional style of singing and dancing. Among the famous Tango singers, the names of *Carlos Gardel* and *Astor Piazzolla* must be cited.

In Peru, creative dance, which represents courtship and love by two dancers, is represented by *La Marinera*, among other folkloric dances originated from the Andes region. In Colombia, the influence of Spanish and German immigrants combined with the Indian tribes resulted in the courtship dance *Cumbia*, which later blended with other modern styles and spread all over South America.

Gastronomy and Fashion

Other domains of creative expression have also to be mentioned. Peru, for example, is proud of its gastronomy, which is derived from the interesting combinations of food from the Andes with other nationalities who came to live there. Brazil is also proud of its gastronomy resulting from the interaction of African with Portuguese food habits, in addition to splendid juices from tropical fruits all over the year. Fashion is another area where S. American countries are exporting really well since their colored summer clothes are known and required internationally.

Finally, the areas mentioned above are just a few among a great variety of creative expressions in South American countries. These productions demonstrate that this continent has specific ways of demonstrating their creativity, as they are an integration of many races who came to these countries and gave their contribution. Despite the difficult socioeconomic conditions that some of these countries experienced, these circumstances did not suppress their creativity; on the contrary, the difficulties gave them the opportunity to search for new ways to express their cultural richness.

Creativity Research in South America

There are a sizable number of research studies related to creativity in South America. This can be verified in the open-access publications available on the Network of Scientific Publications from Latin America, Caribbean, Spain, and Portugal (REDALYC, 2019). A search for the word “creativity,” without limitations of the year and only from countries located in South America (Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, Guiana, Paraguay, Peru, Suriname, Uruguay, and Venezuela), produced a total of 4384 articles.

Subsequently, with the aim to delimit the knowledge area, a second filter was applied to the REDALYC database, selecting three areas of knowledge, for comparison: Psychology, Education, and Organizational/Administration. In Psychology, 622 articles were found, 497 in Education, and 920 in Administration. These publications started from 1998, but important differences between the areas can be noted. In general, in all three areas, creativity only aroused researchers’ interest in the last decade.

The second analyzed criterion in the REDALYC database was the country of publication in three main areas of knowledge. The results indicated that Brazil is the country that most published on creativity areas (Psychology = 364, Education = 210, and Administration = 708), followed by Colombia (Psychology = 145; Education = 177, and Administration = 170) and Argentina (Psychology = 43, Education = 7, Administration = 9). 60% of these publications are written either in Portuguese (35%) or in Spanish (25%). Publications in the English language were primarily related to Administration more than other areas.

Another interesting analysis is to verify the main concerns presented by the authors from each area in the last two years (2018–19). In Psychology, the most frequently mentioned topics were related to personality, intelligence, thinking and cognitive styles, giftedness, character strengths, memory, analogical thinking, attention, intentionality, and well-being. There were also a number of articles related to social issues and their impact on creativity including obstacles to creativity, parental relationships, psychosocial factors, gender, social mobility, social politics, and cultural factors. Only four articles involved aspects related to creativity in the visual arts field.

In educational publications, three main research issues were identified: the teaching-learning process, the teaching practice, methodology and school performance. Publications in the Administration area were mostly focused on innovation with psychological constructs, related to this subject including entrepreneurship, leadership, engagement, social capital, burnout, and motivational profile.

Other aspects related to the organizational context encompassed organizational performance, sustainability, patents, customer participation, factors of organizational success, knowledge, and management. The most current issues were related to technology such as digital technology and social network.

Trends

The trends observed in South America indicated that creativity is understood in a multidimensional aspect, involving the person, the process, and the environment. These dimensions are in continuous interaction; the challenge is promoting a state of optimal combination to facilitate the personal and professional fulfillment of an individual. Indeed, the notion of self-actualization, quality of life, and mental health was prevalent rather than a focus on the quality of a creative product.

In Venezuela, as reported by Vivas (1999), there was a great interest on creativity around 1979, due to the influence of an important politician, Luis Alberto Machado. He created the Ministry of Intelligence which had programs to stimulate creativity in babies through guiding their mothers, and also provided creativity enrichment. Unfortunately, most of the programs to improve creative education were lost with the political change in the country around 1984, although educational efforts are still alive in some schools.

The Assessment of Creativity: The Search for Indigenous Measures

In South America there is a search for indigenous measures which represent the creative expression in each country. A number of instruments have been developed in each country; some of them were translated and adapted, whereas others were constructed specifically for each context.

In Chile there is a Cuestionario de Prácticas Pedagógicas para la Creatividad (Creativity-Fostering Instructional Practices Questionnaire) and the Test de Apropiación para la Creatividad (Appropriation for Creativity Test) (Barahona, 2004). In Argentina the Prueba de Producción de Respuestas Originales (Original Responses Production Teste) (Armesto, 2001) and the Escala de Comportamiento Creativo (Scale for the Evaluation of Creativity Behavior) (Aranguren and Irrazabal, 2012) are available. According to Aranguren and Irrazabal (2012), in Argentina the tools to evaluate creativity are scarce, and it is more common to find adaptations of international instruments.

In Brazil, there is a regulation issued by the Federal Council of Psychology, which approves for professional use of only those instruments which present validity, reliability, and norms for the country. Due to this fact, only four instruments are approved for psychologists’ use, which are the Torrance Tests for Creative Thinking, figural and verbal forms, adapted to Brazil by Wechsler (2006), and another two national tests, Styles of Thinking and Creating (Escala de Estilos de Pensar e Criar-Wechsler, 2006; Wechsler et al., 2012) and Figural Creativity test for children (Nakano et al., 2011). A considerable number of other creativity instruments were created for thesis and dissertation purposes, aimed to evaluate different aspects of creativity, such as barriers to personal

creativity, climate for creativity in the classroom, teaching practices for creativity, and climate for creativity in the work environment as reported by Alencar et al. (2010).

Systematic programs for stimulating creativity are found in programs for the gifted, which are present in Peru, Uruguay, and Brazil (Wechsler et al. (2018)). In Peru, in 1983, the Ministry of Education of Peru recognized the needs of intellectual gifted children and established programs for teacher training and psychological interventions in schools. The program created at the Pontifical Catholic University of Peru had as goal to identify gifted children living in poverty conditions in order to develop intervention programs for them. Peru was also the first Latin American country to organize a residential academy of Arts and Sciences for high achieving students coming from low socioeconomic conditions.

In Brazil, a federal law defining the need to educate gifted children has existed since 1971 requiring centers for gifted students within the 27 Brazilian states. However, there are only a few centers that are fully operating nowadays, usually located at the state capitals. Competition programs supported by the government such as the Mathematic and Literature Olympiads also offer opportunity for the gifted. There are opportunities to obtain scholarships (Scientific Initiation Scholarships) from federal grants to mentor high school or college gifted students, under the supervision of an university professor. Conferences to stimulate gifted education are offered every 2 years by the Brazilian Council for the Gifted (ConBraSD- Conselho Brasileiro para Superdotação, 2019), and there is a considerable production of books related to stimulation of creative and intellectual talent and gifted education.

Conclusions

Creativity in South America can be observed through cultural manifestations in visual arts, dance, music, architecture, urban design, gastronomy, etc. The foundation of the Brazilian Creativity and Innovation Association (CRIABRASILIS- Associação Brasileira de Criatividade e Inovação, 2019) was an important landmark to publicize the work in these areas by Brazilian professionals and scholars. Moreover, there is a systematic increase in research related to creativity, primarily in the domains of Psychology, Education, and Administration. Programs for stimulating creativity exist in different formats, within business organizations or in educational settings, such as gifted programs supported by local government. The Brazilian Association for Positive Psychology also divulges the diversity of Brazilian's creative works in different areas (ABP+; Associação Brasileira de Psicologia Positiva, 2019).

Creativity Studies: Regional Contributions

In a world that has been globalized by information and communication technologies, a form of organic creativity has become an essential need for our well-being (Corazza, 2017; Corazza, 2019), and this points to the necessity for growth in the field of creativity studies, coupled to a sentiment of urgency. In this framework, it is relevant to provide an understanding of how the different areas of the world are contributing to this field. Given the distributive nature of the Information Society, it is increasingly difficult, but not impossible, to map scientific research contributions from a regional point of view. Here we attempt such an exercise, with the objective to provide quantitative information in terms of number of modern scientific contributions in the field of creativity studies, their impact and relative growth, the areas of research that appear to be more important for the present and the future, all seen through macroscopic geographic lenses. This quantitative analysis of regional contributions to creativity studies is approached by exploiting data analytics tools, applied to data extracted from the Web of Science in a period of slightly less than twenty years at the start of the third millennium, based on a search for keywords, and according to the criterion of assigning a scientific journal publication to a region on the basis of the first Author's affiliation. For this selected time period, this approach allows to extract a series of very interesting data on: number of publications per region and per year, principal keywords utilized by researchers, areas of research as classified by the Web of Science, number of citations per region, as well as a classification of top journals for creativity.

Quantification of Scientific Production in Creativity

This quantitative analysis was based on data collected on the Web of Science (WoS) for the period January 1st, 2000 to October 15th, 2018, including all the scientific publications that contain the “creativity” or “creative” term as a keyword or part of a keyword. It should be noted that WoS provides two variables for keywords: “Author Keywords”, corresponding to the keywords selected by the authors themselves, and “Keywords Plus”, a series of keywords automatically proposed by WoS based on the article. Because both categories of keywords are relevant in their own right, these two lists were merged into a single list of keywords for our search. Further filtering was based on retaining only the publications classified as “journal article” by WoS (removing all the books, book series, and patents), and only those for which a geographical location could be inferred. The geographical location was attributed using the country mentioned in the address of the first author. Countries were then grouped by broader geographical region, initially considering seven regions, and then reducing them to only four: Europe, North America, Asia, and the Rest of the World. The selection criteria described above were chosen as an optimal compromise between two contrasting requirements: obtaining results that are i) as exhaustive as possible; ii) as relevant as possible. The net result was a collection of 10.413 scientific articles, which were then analyzed to obtain quantitative data on the number of publications per region and per time sub-period, the principal keywords used by creativity researchers, the areas of research addressed, statistics on the number of citations, and a classification of top journals for creativity studies.

Number of Publications per Region and Time Sub-Period

In Table 1, the number of journal articles on creativity per geographical region listed in the Web of Science and published in the period January 2000–October 2018 is reported, considering the following seven regions, ranked for quantity: Europe, North America, Asia, Oceania, Middle East, Central and South America, Africa.

In order to perform more homogeneous comparisons, last four regions were grouped into a single macro region identified as Rest of the World (ROTW), and the result of this aggregation is shown in Fig. 1. It can be noted that Europe contributes for nearly 40% of the total publications on creativity in the world.

Table 1 Number of journal articles on creativity per geographical region in Web of Science published in the period January 2000–October 2018.

<i>Region</i>	<i>Number of publications</i>
Europe	4463
North America	3123
Asia	1509
Oceania	484
Middle East	436
Central and South America	299
Africa	99
Total	10,413

**Figure 1** Number of journal articles on creativity per main geographical region in Web of Science published in the period January 2000–October 2018 (ROTW: Rest of the World).

By subdividing the time period under observation into four sub-periods (2000–04, 2005–09, 2010–14, 2015–18), it is possible to appreciate the evolution in the time domain of the number of publications per period, as shown in [Fig. 2](#). As can be seen, in general there is very good growth in all regions in the world, in some cases nearly exponential.

Principal Keywords Used by Researchers

Clearly, papers on creativity can address a large variety of different issues related to this complex construct. To get a feeling of the distribution of these possible flavors, it is interesting to see which keywords are the most used in which regions, within the population of selected papers. The four regions have commonalities and differences, as reported in [Table 2](#), for the regional top 15 keywords. Not surprisingly, “creativity” is number one in all regions, while “innovation” and “performance” share second and third positions across the world, with one notable exception: in Asia, the third most used keyword is “employee creativity”, revealing a relatively important focus in Eastern countries on creativity studies for organizations and management. Also of note, and somewhat surprising, is the relatively low ranking of the “education” keyword, as well as the fact that of all the possible components of the creative thinking process, the only directly relevant keyword in this list is “divergent thinking”.

Excluding now the overwhelming presence of the “creativity” keyword, [Fig. 3](#) shows the quantitative distribution of the other 15 keywords in the European ranking through region by region histograms. Again, the most notable divergence pertains to Asian countries, where a clear emphasis on “performance”, “employee creativity”, and “work” is placed, as compared to the other regions.

Areas of Research

The Web of Science allows to extract information about the “Area of research” pertaining to a journal, through its own classification system. Only the top 15 Areas of research were kept in the analysis. It should be noted that some journals are classified in more than

Figure 2 Number of journal articles per region per time sub-period.

Table 2 Top 15 keywords per region.

Europe	North America	Asia	ROTW
Creativity	Creativity	Creativity	Creativity
Innovation	Performance	Performance	Innovation
Performance	Innovation	Employee creativity	Performance
Model	Model	Innovation	Model
Personality	Personality	Model	Education
Divergent thinking	Work	Transformational leadership	Employee creativity
Intelligence	Divergent thinking	Work	Personality
Knowledge	Employee creativity	Behavior	Work
Work	Behavior	Organizations	Divergent thinking
Organizations	Intelligence	Personality	Perspective
Perspective	Organizations	Perspective	Transformational leadership
Education	Knowledge	Self-efficacy	Intelligence
Behavior	Perspective	Intrinsic motivation	Thinking
Management	Thinking	Divergent thinking	Knowledge
Employee creativity	Idea generation	Motivation	Design

Figure 3 Percentage of articles per region mentioning each of the top 15 keywords for Europe (excluding "creativity").

one category, although 70.4% of journals are classified only in one area. Table 3 contains the percentage of papers belonging to the top 15 Areas of research in each region. Ranking is performed according to the numbers applying for Europe. It is of interest to note that “Psychology” is distinctly the number one Area of research dealing with creativity, particularly in North America, again with the exception of Asia, where “Business & Economics” is first. The latter Area of research is ranked very high also in the other regions. “Education” comes in at the third place except for ROTW, perhaps a signal of a need for training in creative thinking in vast areas of the world such as Africa, Central and South America, the Middle East, and Oceania. “Engineering” comes at the fourth place across all regions of the world. Finally, it is very important to underline that, observing this Table, it is evident that creativity is a horizontal topic that is dealt with by many disciplines. This is both a blessing and a curse, given the difficulties that researchers in creativity studies might have to face in being recognized within the boundaries of a single discipline.

Statistics for Number of Citations

Even though in terms of the number of papers Europe ranks first in the world, North America takes the lead in terms of average number of citations per paper, doubling or tripling other regions in the world, as shown in Fig. 4. This is a clear sign of the impact of creativity studies performed in North America.

Considering not only the average but a sort of discretized cumulative distribution function, Table 4 shows the number of papers per region that received a number of citations that is larger than a specified threshold. Again, North America achieves superior numbers in the entire statistics, with 13 papers at more than 500 citations (only 1 in Europe), and two papers above the astounding

number of 1000 citations. Given the different growth rate in Europe with respect to North America, these statistics should be reconsidered in 5–10 years, to verify whether any change occurred.

Further, **Table 5** considers only papers which received more than 50 citations, and maps their number over regions of the world and over scientific journals, considering the ranking that holds in Europe. 24 North America papers are present in the Creativity Research Journal, while 10 European papers are present in these statistics in the Journal of Personality and Social Psychology.

Top Journals in the Field of Creativity

The previous result from **Table 5** starts to point to the final dimension we considered in this quantitative analysis, which pertains to the performance of specific scientific journals in the field of creativity. **Table 6** reports a ranking of the top 20 journals based on the fractional number of articles for every 1000 publications in the field of creativity. It is not surprising but still significant to find that the first four positions are taken by specialized journals, such as the Creativity Research Journal, Thinking Skills and Creativity, the Journal of Creative Behavior, and Psychology of Aesthetics, Creativity and the Arts. Also notable is the fact that these top 20 journals only cover about 20% of the overall publications found in the Web of Science in the reference period: one more signal of the fact that this scientific domain is horizontal to many disciplines, and that creativity is dealt with by many scientific communities.

Finally, it should be noted that the relative ranking of the journals is quite heavily dependent on the region, as reported in **Table 7**. In Europe, the top journal in terms of published contributions on creativity in the selected period is Thinking Skills and Creativity, while the Creativity Research Journal is the highest for North America. Note also that in North America a very high number of contributions appears in the Journal of Creativity in Mental Health.

Conclusions

In conclusion, it can be stated that the field of creativity studies in the period 2000–2018 has grown considerably in all regions of the world. North America has led this effort in terms of impact measured in number of citations, while Europe produced the highest number of contributions. It is important to note that the field of creativity studies appears to be horizontal to many different disciplines; most contributions come from the fields of psychology, economics, education, and engineering.

Remote Associations and Creativity

Mednick (1962) argued that a person’s level of creativity is directly related to their associative hierarchy or associative gradient. That is, creative people have flatter association hierarchies where many associations between concepts are of relatively equal strength, whereas non-creative people have steep association hierarchies where a single association is much stronger than other possible associations (see Fig. 1). According to this theory, high-creative people should produce more, and more varied, associations to a stimulus word than low-creative people. This also suggests that high-creative people produce these associations mostly automatically.

However, simply producing a greater number of remote associations will not always give rise to more creative solutions, and extremely remote associations are unlikely to be relevant to the solution to a problem. In fact, studies indicated that the use of moderately remote associations related to creative achievement. Therefore, Mednick defined the creative thinking process as “... the forming of associative elements into new combinations which either meet specified requirements or are in some way useful. The more mutually remote the elements of the new combination, the more creative the process or solution.” (Mednick, 1962, p. 221). In this definition, simply producing more, and more varied, associations to a stimulus does not mean that a person will produce a more creative solution to a problem. The solution must also be useful for it to be considered a creative solution. While remote associations alone may be insufficient for creative solutions, the production of remote associations is an important and necessary component of creative problem solving.

Mednick (1962) developed the Remote Associates Test (RAT) to measure individual differences in the ability to make remote associations and engage in creative problem solving without requiring the person to have special knowledge specific to any field. To this end, Mednick and his colleagues constructed two college-level versions (Forms I and II) (Mednick, 1962; Mednick and Mednick, 1967) and one high school level version of the RAT (Mednick and Mednick, 1971).

The design of the RAT was based on Mednick’s definition of the creative process in terms of activation of less probable (more remote or distant) associations. Of course, the mutual remoteness of the elements can be taken too far so that some associations are so remote as to be essentially unassociated. Thus, a creative solution must both have a low probability of being produced and be

Figure 1 Association hierarchies for the concept “table”. Taken from Benedek, Neubauer, 2013. Revisiting Mednick’s model on creativity-related differences in associative hierarchies. Evidence for a common path to uncommon thought. *J. Creative Behav.* 47 (4), 273–289.

useful. These requirements are necessary to distinguish between "... original ideas expressed in institutions for the mentally ill ..." (Mednick, 1962, p. 221) and truly creative ideas. Mednick and Mednick (1967, p. 1) stated that, "... the Remote Associates Test is an operational statement of this definition."

Description of the RAT

Mednick argued that the RAT is a measure of creative thought because finding a solution requires the solver to search beyond obvious, strong associations to each word in a RAT item and consider weaker, more remote associations to the words. The first association a person is likely to retrieve for each word in an item usually will not lead to the solution. Thus, RAT items require most solvers to think of more distantly-related associations to discover an association that connects all three words.

The RAT requires making remote associations, but the associations are constrained by the set of words that constitute the item. Mednick (1962) argued that, in terms of associative theory, there are three ways of attaining creative solutions: (1) serendipity, where the various elements of the solution are elicited simultaneously or contiguously by an accidental occurrence of stimuli elements; (2) similarity, where the various elements are evoked as a result of similarity of the elements themselves or of stimuli evoking them; and (3) mediation, where the elements are evoked by mediation of common elements. Thus, the creative person must use both divergent thinking to produce uncommon associations and convergent thinking to select an association that is judged to be the solution to the problem. Although the RAT is often discussed as a test of convergent thinking, in reality it is a rare test of combined divergent and convergent thinking.

Typically, measurements of creativity have been done utilizing either open tests of divergent thinking, such as the Torrance Test of Creative Thinking, or closed tests such as Matchstick Algebra puzzles. In open tests, the examinee is encouraged to produce many possible responses scored on criteria such as originality and number of unique responses (fluency). Thus, scoring can be somewhat subjective (e.g., judgments of originality), often requiring several scorers and assessments of inter-rater reliability. In contrast, closed tests contain items with a single correct response. The RAT is an instance of a closed test with a single word scored as the correct response to each test item. This makes scoring the test easy, objective, and potentially automated, but it also makes the test less sensitive to nuances in creativity.

Each of the three versions of the RAT consists of 30 items, each item being composed of three words such as COOKIES-SIXTEEN-HEART (example from Mednick and Mednick, 1967, p. 1). All three words are associated with a single solution word (in this case, SWEET). Only common English words were used to create the items because they were considered culturally universal within the United States; therefore, the items should require no special knowledge to solve. The Thorndike-Lorge Word Count was used to determine the probable familiarity of the words making up each item, and the Kent-Rosanoff Word Association Test was used to select solution words that were valid but low probability responses to all three words of an item. The 30 items included in the original RAT (College, Adult, Form I) were selected, based on an item analysis, from an initial 100-item battery given for a period of about one year to various groups of students and professionals.

The way in which the words in any test item are associated with the solution varies both within and between test items. For example, the three words in the item COOKIES-SIXTEEN-HEART are associated with the solution, SWEET, by means of semantic association (COOKIES are SWEET), by co-occurrence (part of the compound word, SWEETHEART), or as part of a phrase (SWEET SIXTEEN). Across all items in the RAT, words within any test item (e.g., SAME-STRIKE-TENNIS) can be related to the solution word (MATCH) in a variety of ways, including synonymy (SAME is synonymous with MATCH), semantic association (one can STRIKE a MATCH), and as part of a phrase (TENNIS MATCH). This unpredictability of the type of associations between the words in the item and the solution word requires the examinee to consider a quite wide range of possible solutions. Therefore, the RAT is a strong measure of flexible thinking, which is an important component of creativity. However, this inconsistency in the type of associations required to find the solution means that it is likely that the RAT is measuring multiple aspects of creativity beyond the ability to make remote associations, or variables other than creativity such as intelligence or verbal facility.

In the original versions of the RAT, examinees were given 40 minutes to complete the entire test; an individual could choose to spend mere seconds on one test item and potentially minutes on another test item. A test taker could also potentially return to unsolved items multiple times during the testing period. The score on the RAT is simply the number of items answered correctly. The RAT was designed to be administered to individuals or to groups with equal ease and, with a single solution accepted as correct for each item, the scoring of the RAT is simple and straightforward.

Mednick and Mednick (1971) presented five criteria which guided the selection of RAT items on the High School version of the RAT: (1) Each item can discriminate between examinees in each quartile of the RAT score distribution. (2) The items do not have commonly given incorrect solutions. (3) The average performance for the overall test is 50% correct. (4) Items are consistent in difficulty across samples. (5) The items are not highly correlated with measures of intelligence.

Evaluations and Psychometrics of the Remote Associates Test

Shortly after publication of the Examiners' Manual Remote Associations Test (Mednick and Mednick, 1967), several researchers explored the reliability and validity of the RAT. Since then, there has been a relative lack of research and data examining the psychometric properties of the RAT. For an instrument to provide useful measurements, it must be both reliable and valid. Reliability and

validity are crucial for the interpretability and the generalizability of the constructs being measured. Reliability is the degree to which an instrument consistently measures a construct, both across items within the instrument and across points in time. Validity is an index of whether an instrument measures the construct it purports to measure (in this case, creativity). A measure can be reliable without being valid, but it cannot be valid without being reliable.

Performance: In his original paper (Mednick, 1962) and in the initially available version of the RAT (Mednick and Mednick, 1967), Mednick reported 16.41 mean solutions from tests of 2786 University of Michigan undergraduates, 20.10 from 81 University of Michigan graduate students in Psychology, 13.14 from tests of 73 University of Maryland undergraduates, and 18.0 from test of 288 Bennington College undergraduates. Similar scores were measured in samples from the University of Alberta and the University of Nevada. Mednick reported a mean solution rate of 19.13 from tests of 370 research scientists. These data suggest that Mednick did a reasonably good job of attaining the desired average performance of close to 50% solutions (between 44% and 67%) and a good distribution of scores allowing differentiation between levels of solving ability.

Reliability: There are different ways of measuring reliability, with the consistency of results across items within a test (internal reliability) and consistency between multiple test administrations (test-retest reliability) being the most important measures for the RAT. Reliability scores above 0.70 are generally considered to be acceptable, whereas values above 0.90 are considered excellent.

Mednick (1962) presented odd-even internal reliability correlations of 0.91 and 0.92 from two separate samples of students. In a more recent study, Lee et al. (2014) reported good internal reliability for 30 RAT items (Cronbach's $\alpha = 0.82$), replicating Mednick's reports of RAT reliability.

Validity: A critical question is whether the RAT measures creativity. Mednick and Mednick (1967) presented validity data in several categories: ratings of individuals and products; other associative measures; and measures of intelligence, achievement, and personality. Unfortunately, a substantial proportion (8 out of 12) of the relevant studies cited were unpublished doctoral dissertations, senior honors projects, conference presentations, or technical reports. The four remaining studies were related to ratings of individuals and associative measures.

Ratings of individuals: Mednick found that independent assessments of creativity made by supervising professors and coworkers positively correlated with RAT scores. For example, Mednick (1963) reported a correlation of 0.55 between RAT scores and advisors' ratings of research creativity for 43 psychology graduate students. Mednick and Halpern (1962) reported a correlation of 0.70 between RAT scores and instructors' creativity ratings of 20 architecture students.

Associative measures: Houston and Mednick (1963) examined the relationship between preference for either common or remote associations and RAT performance in 30 undergraduate students. A "high creativity" group consisted of participants with high RAT scores and a "low creativity" group consisted of participants with low RAT scores. Participants performed a verbal association task in which they picked one of two words, either a noun or a non-noun, and would receive an associated word in response. When the participant picked a noun, the experimenter would always respond with a remote association (an association that rarely occurred in word association norms), whereas non-nouns were always paired with their most common associate. There was a reliable interaction between RAT performance and preference for association over time: The "high creativity" group preferred more remote associations while the "low creativity" group preferred more common associations.

Additional assessments and validity data: As mentioned above, Mednick and Mednick (1967) reported significant correlations between RAT scores and creativity ratings of architecture students, psychology graduate students, and scientists in a chemical firm. However, other researchers did not always find reliable correlations between scores on the RAT and other measures of creativity.

Shortly after publication of the Examiners' Manual Remote Associations Test (Mednick and Mednick, 1967) several reviews of the RAT were published in the Seventh Mental Measurements Yearbook. In one review, Baird (1972) criticized the RAT on three grounds: (1) There is mixed evidence regarding its validity in predicting real-life creative achievements. (2) It is poorly related to other measures of creativity or problem solving. (3) It appears to mostly capture academic or verbal intelligence. He went on to say that the RAT is not appropriate for selecting potentially creative people, but it may be more useful for investigating the creative process. In another review, Vernon (1972) praised the RAT for being based on a sounder psychological theory than most tests of creativity. He also pointed out that the authors do not make exaggerated claims for the RAT, stating only that the RAT measures the ability to notice remotely associated elements and to access their relevant to a problem, which is an ability fundamental to the creative thinking process.

Other studies did not find a relationship between workplace or real-world creativity (as rated by supervisors) and RAT performance. Some of these null correlations may be due to non-native English speakers in the samples, which suggests that the RAT is limited as a measure of creativity because it relies heavily on verbal abilities and cultural knowledge. Some studies reported weak or no correlations between RAT performance and established ratings of creativity including measures of divergent thinking (i.e., originality, fluency, flexibility, elaboration, and composite scores) on Guilford's battery, Guilford's Alternative Uses Task, or the Torrance Test of Creative Thinking. However, RAT performance was correlated with solution rates for classic insight problems and performance on the Raven's Progressive Matrices, which we would argue requires flexible thinking and the occasional insight. Additionally, researchers found correlations between the RAT and other measures of the ability to make remote associations (Mednick's theoretical rationale for creating the RAT as a test of creativity).

Hattie and Swanson (1982) evaluated the performance of 464 students (ages 14–17) on the High School version of the RAT on the five criteria presented by Mednick and Mednick (1971, p. 6). They found that (1) the mean discrimination value for all items was 28.83% and 11 of the 40 items had discrimination values less than 20%. (2) Five items had commonly given incorrect solutions, though they do not state what percentage is defined as commonly given. (3) Only nine items fell within the desired 30%–70%

solution range, 12 items were solved by less than 10% of the examinees, and only one item was solved by more than 75% of the examinees. There were also 17 items that Hattie and Swanson felt had more than one satisfactory solution in addition to the solution deemed correct by [Mednick and Mednick \(1971\)](#). (4) The results of the test appeared to be stable across samples of high school students. (5) The correlation between overall score on the RAT and two tests of intelligence were high. Thus, it appears that items in the High School version of the RAT fail to meet criteria 1, 2, 3, and 5 of the 5 criteria established by [Mednick and Mednick \(1971\)](#) for item selection.

Contrary to Mednick's claim that the RAT does not depend on intelligence (as indicated by no [or negative] correlation with GPA), studies found that performance on the RAT was positively correlated with IQ scores (including verbal intelligence, quantitative intelligence, and fluid intelligence), word fluency, performance on English (verbal) and math standardized tests, and GPA. Performance on the RAT was also positively correlated with measures of processing speed and working memory. As the above studies indicate, evidence for the validity of the RAT as a measure of individual differences in creativity has been mixed and has been repeatedly called into question.

Strengths and Weaknesses of the RAT and Variations on the RAT

Strengths: As discussed in [Bowden and Jung-Beeman \(2003\)](#), the RAT and its variations (discussed below) have several practical advantages over more typical insight problems: (1) They generally can be solved in a short time, so many problems can be attempted in a single experimental session of 1 hour or less. (2) They are simpler than traditional insight problems, allowing better control of possible confounding variables. (3) They have single-word and unambiguous solutions, allowing the collection of more precise response time data and easier scoring of responses. (4) they are physically compact, so they can be presented in a small physical space and for a short period of time. These features allow better control and measurement of timing variables (e.g., measuring the time between presentation of the problem and production of a solution, controlling timing of hint presentation or timing of solution presentation for solution judgment tasks, etc.) and display variables (e.g., position of the problem and/or solution on the display). These features also allow for the use of various paradigms (e.g., priming, solution recognition, and hemispheric differences paradigms).

Although RAT items are not as complex as traditional insight problems, evidence that RAT items are solved by insight has been presented in the form of correlations of rated insight with degree of solution priming and in correlations with performance on both classic verbal insight problems and modern insight problems (e.g., Rebus Puzzles and anagrams).

RAT items also exhibit the three properties of insight problems that distinguish insight solutions from non-insight solutions: (1) They misdirect (or fail to direct) retrieval processes. For example, in the problem PINE–CRAB–SAUCE, the word PINE might direct the initial search of memory toward items such as PINE TREE or PINE CONE, while the word CRAB might direct search toward KING CRAB or CRAB CAKES. (2) Solvers often cannot report the processing that has led them to the solution. (3) Upon solving RAT items, solvers often have the Aha! experience ([Bowden and Jung-Beeman, 2003](#)). This third property is often considered the central defining feature of insight problems (see [Bowden and Grunewald, 2018](#)).

RAT problems elicit similar rates of Aha! experiences as classic verbal and spatial insight problems and anagrams and are marked by a similar sudden increase of “feelings of warmth” during solution. Thus, solving RAT or RAT-like items appears to involve the same component processes critical for, and the same phenomenological experience of, insight solutions to more complex problems.

Weaknesses: As mentioned above, one of Mednick's goals when designing the RAT was that it would not require a person to have any special knowledge specific to any field. However, some associations do require special knowledge (if not special training), such as knowledge that the word ACE is a term used in tennis or that KING CABBAGE is a type of cabbage.

Another weakness is that some of the items from the original versions of the RAT have become outdated, such as ROOM–SATURDAY–SALTS (solution BATH). The idea of Saturday being a special bath day is antiquated. Some of the associations are not just remote but are unnecessary for the solution. For example, in the item BALD–SCREECH–EMBLEM (solution EAGLE) it seems that the association between EMBLEM and EAGLE is not necessary to produce a reasonable solution. It could be plausibly argued that other solutions are equally acceptable (e.g., TIRE because a tire could be BALD, a tire can SCREECH, and a tire could plausibly be an EMBLEM for an automotive company). In other words, EMBLEM fits with the solution EAGLE, but EMBLEM is unnecessary for one to generate the solution. Another example of an antiquated or vague association is the item WICKED–BUSTLE–SLICKER (solution CITY), as it is unclear why a city is wicked or what a wicked city is.

Other problems stem from what might be referred to as quality control issues. An item in the original RAT, PUSS–SPIT–SPOILED, seems to contain an error. The solution, SOUR, does not appear to be associated with SPIT: a person can be a SOUR PUSS and something SPOILED can be SOUR, but the association between SPIT and SOUR is unknown to the authors. It seems that the item should be PUSS–TART–SPOILED. Another quality control issue is that some words appear both in problems and as solutions. For example, the solutions to item 8 (CHEESE) and item 26 (MUSIC) are included in the three words in item 23 (BLOOD–MUSIC–CHEESE; solution BLUE). This leads to the possibility of priming from one problem to solutions of other problems.

Finally, RAT items may require something that is analogous to more than one insight. For example, with an item such as STICK–MAKER–POINT (solution MATCH), the solution creates three compound words that are members of different categories, compared with BASE–BASKET–FOOT (solution BALL) whose solution produces compound words from a single category.

Variations on the Remote Associates Test

The RAT relies heavily on verbal knowledge, which suggests that it is limited as a measure of creativity in non-native speakers of English. Indeed, performance on RAT problems can depend on the solver's familiarity with cultural idioms and the degree to which RAT solutions are culturally associated with their problem items. Thus, over the years, researchers developed several linguistically and culturally customized versions of the test. The RAT has been adapted for or translated into a number of other languages including Hebrew, Dutch, Chinese, German, Japanese, Polish, Tamil, and Jamaican-English.

The basic theory underlying the RAT has also been used to generate variations on the RAT. The Functional RAT (FRAT) was created to depend on functional, non-language relationships grounded in reality rather than language-based associations. For example, BIRD and EGG are associated not only in written and spoken language but are related in reality. Therefore, a person without exposure to language could still understand the relation between a bird and an egg. However, not all FRAT items are purely functional associations. For example, the item FRAME-PHOTO-PORTRAIT (solution PICTURE) forms the compound phrase PICTURE FRAME, and the item COMET-LIMIT-VELOCITY (solution SPEED) forms the compound phrase SPEED LIMIT. Additionally, some problems have more than one acceptable solution. For example, for the item AROMA-FUMES-GARLIC (solution SMELL), participants gave ODOR and SCENT as solutions, both of which yield similar functional relationships to the three item words and must be considered correct. This ambiguity in what is acceptable as a correct solution may be a good thing. The FRAT would be largely a closed test that allows room for subjective judgments of creativity. This would, however, require non-automated scoring and more consideration of solutions provided.

The visual RAT (VRAT; [Oltețeanu et al., 2015](#)) is in early stages of development and presently consists of 20 items, each composed of three pictures of objects and/or scenes. For example, one practice item contains pictures of a HANDLE, a GLOVE, and a PEN. The solution to this item is HAND because it is a visual associate that co-occurs with the visual entities (i.e., a HANDLE is operated by a HAND, a GLOVE is worn on a HAND, and a PEN is held in a HAND).

A modification of the Remote Associates test that presents participants with a more consistent task is a continually updated set of Compound Remote Associates (CRAs; [Bowden and Jung-Beeman, 2003](#)). The CRAs contains a greater number of problems than were available in the original RAT and presents participants with a more consistent task. That is, the solution word is always associated with all three words of the problem triad through formation of a compound word (or two-word phrase). For example, AGE-MILE-SAND form the compounds STONE AGE, MILESTONE, and SANDSTONE with the solution word STONE. The original set of 144 CRA problems, along with solution percentages and mean solution times by problem at different solution periods, can be found in [Bowden and Jung-Beeman \(2003\)](#). These normative data can be used in the selection of problems according to difficulty or mean time necessary for reaching a solution. Additional information has been collected about percentage of solution by insight or analysis, giving a rough indication of the 'insightfulness' of each problem.

Conclusions

As [Oltețeanu et al. \(2015, p. 2\)](#) pointed out, "Humans are capable of creativity across a wide variety of tasks and domains, including the linguistic (e.g. riddles, novels), visual (e.g. visual arts, design), auditory (e.g. musical), tactile (e.g. fashion and fabrics, texture), gustatory and olfactory (e.g. culinary creativity, perfumery), etc.," to which we should add the domain of motor skills (e.g., athletics, dance). Creativity is an inherently multivariate phenomenon that involves a variety of personality characteristics and cognitive attributes, which includes the ability to produce remote associations between concepts. Because the nature of creative processes may differ markedly from instance to instance, a truly general test of creativity must be able to assess creativity across multiple modalities, tasks and domains. This is a virtually impossible goal to achieve.

The RAT measures the ability to access words associated by co-occurrence or conceptual overlap; therefore, it depends heavily upon linguistic skills and cultural knowledge (such as colloquialisms). Not surprisingly, the RAT has failed as a general test of creativity. However, the RAT also measures the ability to access and use remotely-associated concepts at a basic level independent of language, which can come from different modalities and domains such as unusual color, texture, or taste combinations. This ability to access and use remotely-associated concepts is important for producing creative solutions in all domains. Therefore, the RAT and more recent variations of the RAT remain an important instrument for research on the basic, component processes involved in creativity, insight, and problem solving.

Since its creation, the RAT and its variations have been used to study various facets of creativity including the roles of emotion, attention, and memory, as well as the neural correlates of creativity. A recent meta-analysis of 45 studies by [Arden et al. \(2010\)](#) found that the RAT and variations on the RAT are the second most used test of creativity, following the Alternate Uses Test. Although the original goal of using the RAT as a standalone test of general creativity has not been realized, it remains a valuable and widely used tool for understanding more about the processes that underlie creativity.

Introduction

Creativity reflects a unique human experience. Creative processes are nuanced and dynamic; they often depend on the individual's interpretations of a situation's opportunities and coincidences. Being creative means to transfer something inherently subjective (e.g., meanings, significances, impressions, imagination, improvisation, insight, inspiration, intuition) into an objective product (e.g., a painting, poem, piece of music, dance, solution, speech), while the assessment of product creativity in turn is based on subjective and holistic impressions. In short, creativity is a phenomenon that is essentially tied to a subjective quality.

Despite the qualitative nature of creativity, empirical studies on creativity mostly apply quantitative methodologies. In her empirical review, Long (2014) showed that empirical studies published in five prestigious creativity journals between 2003 and 2012 were predominantly quantitative. During this period, qualitative studies accounted for only 13% of the empirical studies. This neglect of qualitative studies has been persistent in each of the ten years of investigation and in all of the five considered journals. In addition, the empirical review from Kahl et al. (2009) revealed a significant decrease in the number of qualitative creativity studies within dissertations between 2005 and 2007 as compared to a sample from 1986. However, when the fact is taken seriously that many facets of creativity are subjective in nature and cannot be comprehended by using questionnaires and abstract constructs only, the bias towards quantitative methodologies is problematic. As long as the use of quantitative and qualitative methodologies is imbalanced, our understanding of creativity remains one-sided and incomplete.

In order to demonstrate the variety and potential of qualitative research, this entry describes five qualitative methodologies and discusses their relevance for creativity research. These are case studies, ethnography, phenomenology, grounded theory, and narrative studies. Although the article is not a review of qualitative studies, examples are given when presenting the methodological approaches. Before concluding remarks, general issues of validity, rigor, and ethics in qualitative research are outlined.

Foundations of Qualitative Research

Ontological and Epistemological Assumptions

Qualitative research is generally associated with specific ontological and epistemological assumptions that stand in contrast to those of quantitative research. Ontology concerns the question of what reality is; epistemology concerns the question of how to gain knowledge about reality. Ontologically, qualitative researchers assume that social reality is constructed by those involved. As there is no single reality or truth, knowledge is subjective and personal. In terms of epistemology, qualitative researchers regard themselves as a truth-shaping part of the social reality to be investigated. It is assumed that subjectivity is a necessary condition to develop an adequate understanding of a phenomenon and cannot be separated from the researcher, the participant or the situation. Scientific facts can therefore only be acquired through the researcher's interpretation of meanings within a unique social context. Qualitative research thus follows a constructivist, interpretive or postpositivist paradigm. For qualitative researchers, creativity manifests itself in each person, episode, situation or social and cultural background in a manifold and unique way. Quantitative researchers, on the other hand, follow a positivist paradigm. They assume that social reality exists independently of the researcher and is accessible to an objective investigation from an outside perspective. Scientific facts are regarded as invariable and objective. Quantitative

researchers thus assume that creativity consists of a certain amount of factors that vary among people and predict creative outcomes in a more or less reliable way. Creativity is assumed to exist independently of social, cultural and historical contexts.

The aim of qualitative and quantitative research is quite different. Qualitative research is conducted in order to gain and agree upon a holistic understanding of subjective perspectives in certain contexts. As the uniqueness of each situation is recognized, qualitative researchers do not claim that findings from a specific situation can be transferred to other situations as well. The focus is on exploration, enlightenment, awareness, and intersubjective agreement in order to develop a rich understanding regarding the meaningfulness of (creative) actions, words, events, products, places or people. The researcher is at the center of the research process, and the quality of gathering, describing and interpreting data determines the quality of the conducted research. Whereas the former are important, the researcher's primary task is interpretation, in order to discover and reveal the meanings beneath the surface. In contrast, quantitative research is mainly conducted to explain and predict a specific phenomenon in a structural manner by detecting universal laws about the causal relations of variables. Here, the focus is on the production of knowledge on how to realize a desired effect in order to predict or enhance creativity.

Method and Methodology

Although method and methodology are often treated as synonyms, both concepts have to be distinguished. Methodology refers to the general assumptions and theoretical perspectives of a study. It includes the ontological and epistemological assumptions explained above and implies a specific research design. In contrast, a method only refers to a specific research tool that is used within a methodology to collect, analyze and interpret data. The concept of methodology is therefore broader than the concept of method and guides the selection of research methods.

The three most common qualitative methods are in-depth interviews, observations and document analyses. In-depth interviews are used to elicit a comprehensive picture of the participant's perspective regarding the research object. Usually, in-depth interviews are conducted face-to-face between the researcher and the participant. They require a certain degree of openness to ensure that the participant's rather than the researcher's perspective is revealed. Although the researcher needs to specify some general topics, and in doing so pre-structures the interview, the interview process must be flexible enough to account for the interviewee's priorities and concerns. Observations are a way to collect data by watching people, events, behaviors, interactions or artifacts in their natural setting. There are non-participant and participant observations. In non-participant observations, the researcher observes the participants without directly interacting with them. In participant observations, the researcher becomes a constructive part in the site under study. Participant observation is especially suitable when the research questions can only be adequately answered through the participation of the researcher with the subjects in the setting of interest. The researcher, being both observer and participant, learns through first-hand experience. Document analysis examines documents that contain relevant information about the research question. The purpose of document analyses is to gather data on the background and historical context of the study. Examples of documents are reports, protocols, e-mails, diaries, letters, formal statements, interviews, films, videos, novels, photographs, graffiti, paintings or designs. The analysis of documents is an unobtrusive method, where the researcher is not required to intrude into the research context. In general, qualitative methods generate non-numeric (i.e. qualitative) data, as opposed to quantitative methods operating with numerical (i.e. quantitative) data.

However, for a study to be considered qualitative, it is not sufficient to apply qualitative methods. When, for example, qualitative methods are used in the stage of data collection, but the resulting categories are coded and processed numerically, the study is an example of quantitative instead of qualitative methodology. Whereas a study may apply both qualitative and quantitative methods, it cannot follow both a qualitative and a quantitative methodology in the described sense (although there is also the possibility of applying a mixed-methods research design as yet another methodological approach following a pragmatic worldview). The decisive feature of qualitative research is therefore methodology and not the methods used. For this reason, in the following qualitative methodologies are described and discussed in terms of their relevance and potential in creativity research. Following Creswell and Poth (2018), five qualitative methodologies are distinguished: case studies, phenomenology, ethnography, grounded theory and narrative research.

Overview of Qualitative Methodologies

Case Study Research

Case studies are one of the most frequently used qualitative methodologies in creativity research. In case study research, a detailed, concrete, and rich description of one particular case (single-case study) or several cases (multiple-case study) is developed with the intention of capturing the complexity and situatedness of the studied object. A case refers to a real-life, contemporary setting and serves as the main unit of analysis. In order to describe a case within certain parameters, it has to be a bounded system. A case may be bound to a specific entity (e.g., a person, partnership, group or organization) or, at a less concrete level, to a relationship, decision process, behavioral condition, event or project. Case study research is the investigation of a case over time through the use of multiple methods and information sources, including in-depth interviews (e.g., interviewing a creative genius), participant observations (e.g., being involved in the creative process) and document analyses (e.g., autobiographical records of creative individuals). The research usually begins with the identification and the definition of a specific case. Following this, it has to be decided whether the study consists of a single case or multiple cases. Whereas a single-case study focuses on the characteristics of a unique case,

a multiple-case study includes the comparison of the identified cases to discern consistent patterns or regularities. In a multiple-case design, each case is assumed to cover a complementary facet of the main research question.

Although case study research does not call for a specific theoretical foundation, the use of a theory can help to complete certain methodological steps, such as the development of the main research question, the selection of a case or the definition of case-relevant data. However, the use of a general theoretical perspective to analyze the collected data is twofold. On the one hand, it helps to organize and make sense of the collected data. In this way, a case study can attempt to extend or challenge a theoretical perspective. On the other hand, such a perspective can also limit the ability to make discoveries that are beyond the theoretical scope.

The literature provides a number of examples using case study methodology to identify the main characteristics of (eminent) creative persons and to develop a rich understanding of their creative processes and the resulting products. A famous example of a multiple-case study in creativity research is Howard Gardner's book *Creating Minds*. Gardner compared and contrasted the lives of seven eminent individuals who made highly creative contributions in the 20th century: Sigmund Freud, Albert Einstein, Pablo Picasso, Igor Stravinsky, T. S. Eliot, Martha Graham, and Mohandas Gandhi. He showed that creativity is a domain-specific phenomenon that embodies different forms of intelligence: interpersonal intelligence (Freud), logical-mathematical intelligence (Einstein), spatial intelligence (Picasso), musical intelligence (Stravinsky), linguistic intelligence (Eliot), bodily-kinesthetic intelligence (Graham), and intrapersonal intelligence (Gandhi). Despite this divergence, Gardner also showed that these individuals shared specific developmental experiences and dispositional traits. For example, all showed a high level of self-absorption in their activities.

A theoretically based approach to use case studies in creativity research is Howard E. Gruber's evolving systems approach (ESA). ESA is designed to develop an in-depth understanding of the uniqueness of the individual creative person at work. It assumes that each person's purpose, affect, and knowledge evolve over time, lead to individually different paths and result in unique creative products. Purpose, affect, and knowledge are used as major subsystems to structure cases of creative individuals to depict unique attributes. The groundwork of Gruber's approach for the case study of evolving systems was his work on Charles Darwin. Furthermore, ESA has been applied to study the life and works of Albert Einstein and Michael Faraday, among others (See Evolving Systems Approach).

In creativity research, case study methodology is not restricted to investigating extraordinary or eminent creativity, but can also be used to understand everyday creativity. For example, several studies have been conducted to explore individual or collective problem solving in organizational or educational settings. [Crompton and Crompton \(2008\)](#) analyzed the problem solving behavior of engineering students to illustrate the application of universal indicators of creativity in a specific domain. Case studies are also suitable for cases of gifted children and adolescents.

Ethnographic Research

Ethnographic methodology is rooted in anthropology. The intent is not to explore a single case, but to develop an in-depth understanding of individuals, processes, products or environments in different cultures. The term culture refers to a system of synthesized facts, experiences and traditions that altogether constitute a coherent worldview. The ethnographic researcher analyzes and interprets the shared and learned patterns of meaning, values, beliefs, behavior and language among the members of a culture-sharing group. The culture-sharing group thus serves as the main unit of analysis. To be considered as a culture-sharing group, the group must have been interacting long enough to develop a common identity and shared patterns of interaction. A cultural group may be small (e.g., a few artists working together), but typically refers to a larger amount of individuals who interact in a specific cultural context over time (e.g., a community of artists or teachers in an art school). Although interviews and document analyses are relevant sources, ethnographic research particularly involves extended participant observations of the group, in which the researcher is immersed to gain insights from a first person's perspective. The research process in ethnography is essentially based on a theoretical perspective that guides the researcher's attention towards a specific direction. This need for a theory distinguishes ethnography from other qualitative methodologies.

The central assumption of the ethnographic approach to creativity is that sociocultural contexts determine and influence creative behavior, whereas at the same time creative behavior shapes culture and society. Ethnographic studies can help to develop a holistic understanding and interpretation of creative individuals, processes, products or environments and their reciprocal relationships within a specific cultural context. Examples of research questions are: In which way does the creative individual, product or environment determine the creative process? How do cultural values and beliefs shape perceptions about the creativity ascribed to products? Does culture enhance or inhibit the unfolding of creative processes in a specific way? A suitable theory has to be selected, depending on which research question is to be answered.

The theoretical foundations of an ethnographic study of creativity may be diverse. However, three theoretical approaches seem particularly suitable in this context: Mihaly Csikszentmihalyi's systems model of creativity, Pierre Bourdieu's theory of cultural production, and Vlad Petre Glăveanu's Five A's Framework. According to the systems model of creativity, the creative environment consists of the cultural system (the domain) and the social system (the field). The domain is a culturally defined symbolic system (e.g., the periodic table in chemistry, musical notations in music, mathematical notation in mathematics), the field consists of people who influence a domain (e.g., publishing houses, art critics, scientific communities). Creativity is conceptualized as a process that occurs through the interaction of individuals, domains, and fields. An individual draws on a set of rules and practices from the domain to produce a novel variation in the content of the domain. This novel variation is selected by the field for inclusion into the

domain. Creativity only occurs when an individual makes a change in a domain through the selection of the field. From this perspective, creativity can only be understood in the context of culture (See Systems Approach).

In his ethnographic field work, Bourdieu demonstrated that creativity emerges from the complex interplay between a field of works (as a cultural-sharing group) and the individual's habitus. The field of work pre-structures possibilities and restraints of action, and the individual's schemes of action and perception (= habitus) determines how well the field's demands of action can be fulfilled (Bourdieu, 1996).

The Five A's framework also follows a sociocultural, systemic perspective and integrates the concepts of actor, action, artifact, audience, and affordances (as the Five A's) into a coherent framework, whereas it is a defining feature of the framework that none of the Five A's can be investigated in isolation. For example, the actor only exists in relation to an audience, and action is always embedded in a social and material world. The inclusive character of the framework is mirrored in the given definition of creativity: "Creativity is concerned with the action of an actor or group of actors, in its constant interaction with multiple audiences and the affordances of the material world, leading to the generation of new and useful artifacts" (Glăveanu, 2013, p. 76).

Although the importance of ethnographic studies is often stressed in creativity research, the methodology is rarely used. As one of the few examples, McIntyre (2008) ethnographically studied contemporary Western popular music songwriting. The study was based on Csíkszentmihályi's systems model, which was partially coupled with Bourdieu's approach. It concluded that knowledge of the domain of contemporary Western popular music, as well as the access to the field that holds this knowledge, is crucial for a songwriter to be (and count as) creative.

In the end, creativity is in the eye of the beholder, and different culture-sharing groups may vary in their patterns of perception and evaluation of creativity. The ethnographic approach is thus of high relevance for creativity research, and despite its rare use there is a growing interest in culture and society within creativity research. Besides sociocultural studies, cross-cultural studies are also of great interest. Contrasting Western and non-Western cultures, ethnographic studies may help to overcome the prevalent ethnocentric character of creativity research and to identify similarities and differences of creativity between them.

Phenomenological Research

In general, phenomenology is the study of phenomena. It is a qualitative methodology, which initially carries out observations and draws conclusions from them in order to acquire category systems that permit a phenomenon to be named and described. Phenomenological methodology focuses on the subjective, experiential, lived aspect of a particular phenomenon. A phenomenon can be defined as a state of affairs whose factuality appears to someone at a specific time to be unchangeable even with an arbitrary variation of all possible assumptions, and imposes itself on him in such a way that he or she is unable to deny its existence seriously. An example of a creativity-related phenomenon is the flow experience, which was introduced to creativity research by Mihaly Csíkszentmihályi. Flow describes the pleasuring experience of being fully immersed in a specific activity, associated with a feeling of energized focus and full involvement (See Flow). Although phenomenology concerns subjective experiences, the aim is to explore the common meaning for several individuals of their experience of a specific phenomenon by reducing various subjective experiences to an understanding of their universal essence, to make explicit the implicit structure of human experience. The phenomenologist uses a variety of qualitative methods to collect data from individuals who experience or have experienced a specific phenomenon, in order to derive essential structures of subjective experience. Typical data sources are experiential reports in written form, or in-depth interviews.

Phenomenological methodology is well-suited for research into the creative process, because the latter represents a significant and unique human experience. The creative process, as a phenomenon, has been described by eminent individuals in extremely different domains, including natural sciences, literature, painting, and music. Famous phenomenological depictions of the creative process stem from Hermann von Helmholtz and Henri Poincaré, based on which Graham Wallas formalized the four-stage model of the creative process (i.e. preparation, incubation, illumination, verification). Besides studying experiential reports of eminent individuals, phenomenological studies in creativity research often use in-depth interviews. For example, Nelson and Rawlings (2007) conducted semi-structured interviews to explore the creative process of eleven artists. They detected several recurring themes such as the sense of recognition of emerging structures in the artwork or the prominent role of intuition. Beside the creative process, the phenomenological approach can also be applied to study the experience of a creative product as valuable, fascinating and/or unique. For example, the aesthetic experience of admiring artwork, enjoying a piece of music, being fascinated by a dance performance or applying a creative solution represent discrete phenomena that are accessible through phenomenological inquiry.

Phenomenological methodology requires suspending all judgments about reality until they are founded on an experiential basis. Edmund Husserl called this process of suspended judgment *epoché*, which represents a general predisposition one must assume before conducting phenomenological research. Hence, a theoretical basis is not needed for phenomenological inquiries. However, phenomenology has a strong philosophical component, and phenomenological studies can as well be theoretically based on phenomenological works of philosophers such as Edmund Husserl, Max Scheler, Martin Heidegger, Alfred Schütz, Jean-Paul Sartre, Maurice Merleau-Ponty or Hermann Schmitz. Bindeman's study (1998), for example, analyzed inherent characteristics of the different stages within the process of creativity, as described by eminent creative individuals such as Henri Poincaré or Pablo Picasso on the basis of Husserl's phenomenological studies. Julmi and Scherm (2015) applied insights from the phenomenology of Schmitz to suggest that creativity is a domain-specific ability with three different domains on the uppermost level: corporeal creativity as the ability to present atmospheres (e.g., music, painting, dance), hermeneutical creativity as the ability to adapt to and create

situations (e.g., writing, interpersonal relationships), and analytical creativity as the ability to deal with constellations (e.g., math, science). Such conceptions may serve as a theoretical perspective for phenomenological inquiries to dig further into the subjective experience of creativity.

Grounded Theory Research

Like phenomenology, grounded theory methodology focuses on the study of the individual's lived experience in the natural setting and emphasizes the need for an open inquiry. The difference is that phenomenology seeks to understand a phenomenon's essence, whereas the aim of grounded theory is to generate or discover a theory for a (creative) process or action. [Strauss and Corbin \(1994\)](#) defined grounded theory as "a general methodology for developing theory that is grounded in data systematically gathered and analyzed. Theory evolves during actual research, and it does this through continuous interplay between analysis and data collection" (p. 273). The aim of grounded theory is to develop a theory that is "grounded" in the lived experience of the studied process or action, and therefore is tailored to the research object.

Because the result of grounded theory is a theory, the research process itself cannot be based on a theoretical perspective. Instead, the researcher writes down memos as data is collected and analyzed in order to formulate the process from the researcher's point of view (memoing). Data collection, data analysis and memoing are supposed to be undertaken simultaneously and iteratively, going back and forth between collecting data and refining the theory. The research process includes open coding, axial coding, and selective coding. Open coding refers to the identification and labeling of the data in order to build data categories. Axial coding is a comparative process in which data categories are related to one another in order to detect causal relationships. Selective coding is the procedure of choosing one category to be the main category and systematically relating it to the other categories. The resulting theory can be presented as a diagram, propositions, hypotheses, a discussion or, when the research process is less structured, a conjunction of implicit meanings about a category.

Similar to phenomenology, grounded theory methodology is especially valuable for the generation or discovery of theories regarding the creative process. Although the number of grounded theory studies in creativity research is relatively small, the approach seems to increasingly attract scholars from various creativity-related fields. For instance, [Mace and Ward \(2002\)](#) used grounded theory methodology to develop a complex descriptive model of the art-making process from the initial stages of idea inception through to the resolution of the artwork. One finding was that problem solving is a component within the art-making process rather than something the artist is working towards as such. Similarly, [Sawyer \(2018\)](#) developed a grounded theory of the art-making process that revealed the creative process to be wandering, unpredictable, non-linear, and embedded in the physical act of generating work. [Tracey and Hutchinson \(2018\)](#) developed a grounded theory on written reflections produced by graduate students in learning design in response to several prompts on uncertainty. They found that students experience uncertainty as an influence on personal agency, that uncertainty is perceived to provoke complex, ambivalent emotional responses, and that students identify both internal and external strategies for managing uncertainty.

Narrative Research

Narrative research is an umbrella term encompassing methodologies that rely on spoken or written words. Narrative research usually focuses on one or two individuals. The aim is to tell a story of individual experiences through the identification and interpretation of patterns of meaning. This form of research explores expressed experiences in lived and told stories of individuals. As narratives always occur within specific situations, narrative research also tries to consider the social and cultural narratives in which individual experiences take place. Stories, as the main unit of analysis, are gathered through various data sources. The research design typically involves interviews with participants. Stories can be told directly, but often emerge as a co-construction through the interaction of the researcher and the participant. Narrative stories are also gathered through observation or document analysis. The collected stories are often structured chronologically, emphasizing momentous incidents or turning points. The analysis of the story depends on the narrative strategy. For example, a story can be analyzed thematically (what is the story about?), dialogically (who is the story for?), or by focusing on specific values, plots or characters.

Regarding the creative process, narrative studies can enhance our understanding on how individuals frame, recall, and report their creative experiences within a certain social and cultural context. The interpretation of narratives can help to explore the meanings individuals ascribe to the experience of creativity, and how these meanings are related to a greater context. Recently, [Chakraborty \(2017\)](#) highlighted the potential of narratives for conducting research into the creative process: "While narrating their stories, the participants piece together fragments from their working lives to add sense to their stories and thus provide scope to widen the researcher's interpretation of the creative process" (p. 2965). Nevertheless and despite their potential, to date there are virtually no narrative studies in the field of creativity research. As a notable example, [McAdams and Logan \(2006\)](#) examined the question of how eminent creative academics narrate their professional and personal lives, concluding that "people find meaning and purpose in their lives through the construction, internalization, and constant revision of life narratives" (p. 106).

An interesting approach that combines elements from ethnographic and narrative research is autoethnography. In autoethnography, the researcher describes and analyzes his or her own narratives in order to understand culturally shaped experiences. The researcher retroactively and autobiographically writes about meaningfulness experiences from the past (e.g., epiphanies, existential crises, or extraordinary encounters) and contrasts them with similar experiences from other people and/or existing research. In this

way, the researcher helps to better understand cultural patterns of meaning, values, beliefs and behavior for both insiders and outsiders. Autoethnography is not only itself a creative practice, but is also suitable for studying creative practices in a cultural context.

Issues in Qualitative Research

The fact that qualitative research mainly relies on interpretations both of the researcher and the participant raises at least three concerns: research validity, research rigor, and research ethics.

In terms of research validity, qualitative research is not judged by strict standards such as those applied in quantitative research. The demand for generalizability is not adequate for qualitative research and distracts from its purpose. For example, methodologies such as case studies focus on contextual uniqueness and are not designed to be replicated. Validity in one context does not imply validity in another context. Instead, it is argued that qualitative research should be judged using different criteria such as credibility, transferability, dependability, and confirmability. However, such criteria are themselves disputed. Some scholars even reject the idea of research validity in qualitative studies. They argue that if it is ontologically assumed that there is no single external reality, it would be inconsistent to be concerned with the truth or falsity of qualitative results with respect to such a reality.

Regarding research rigor, ontological and epistemological assumptions have to be discussed and made transparent by the researcher. In terms of methods applied, it is assumed that relying on one source of data is not sufficient to develop a holistic understanding of a particular phenomenon. Where possible, interviews, observations and document analyses should be combined. The process of gathering data in multiple ways relying on multiple sources is called triangulation. The discussion of results with other researchers helps to strengthen the derived conclusions and to consider different points of view. Notes, memos, documents, and so forth, should be made available to other researchers to reconstruct the research process and to verify that research was conducted in an acceptable manner. In all of this, however, it must not be forgotten that creativity research is itself a creative practice. The traceability of the research process is therefore limited.

Last but not least, there are several ethical issues that need consideration. First, the rights and permissions of the participants must be protected, and their permission to conduct the study must be obtained. The privacy and concerns of the participants should be treated with respect. Second, the researcher must be honest, and the relationship between researcher and participants should be based on mutual trust (which also determines the quality of the data). The intents, requirements, and risks of the study should be transparent to the participants at all stages of the research process. Third, the researcher is obliged to take up a nonjudgmental attitude to avoid stereotyping. Finally, as participants usually sacrifice their free time for the study, the researcher should give something in return. Sharing the results with the participants is mandatory.

Concluding Remarks

Definitions of creativity often focus on the creative product as the outcome of the creative process. As Sawyer (2012) pointed out, there is a growing interest in a sociocultural definition of creativity, according to which creativity “is the generation of a product that is judged to be novel and also to be appropriate, useful, or valuable by a suitably knowledgeable social group” (p. 8). Products are never creative as such; they have to be labeled creative by someone, and the way in which creativity is understood determines how individuals engage in the creative process. Hence, creativity is a (socially) constructed concept that can only be adequately understood by considering its unique social, cultural and historical context.

As the creative process is inherently subjective, it is not surprising that qualitative methodologies are especially well-suited for exploring the creative process. Although some scholars may refer to quantitative methodologies as the gold standard of approaching creativity, such a view is misleading, because quantitative and qualitative methodologies are complements rather than substitutes for the development of a comprehensive and multifaceted picture of creativity. Given the strong relevance of subjective experiences for the understanding of creativity, the prevalent dominance of quantitative methodologies is not acceptable. This overview will hopefully encourage scholars in creativity research to engage in qualitative research. As the selection of an appropriate methodology to study the creative process is driven by the interest of the researcher, the explication of five methodologies and their relevance for creativity may help the process of selecting a specific methodology.

Two Key Overlapping Concepts: Resilience and Self-regulation

Engaging in the creative process is often viewed as an expression of resilience (McFadden and Basting, 2010). Individuals who respond to adversity with attentional flexibility, while accessing effective problem solving skills are deemed resilient during the adverse event. In the aftermath, generating creative solutions to restore balance within the individual and community are also factors of resilience. Despite exposure to traumatic events, resilient individuals exhibit the quintessential ingredients of creativity; they manifest novel and valuable approaches to remedy the traumatic event and find meaning and purpose in the days and years following the traumatic event. This behavioral trajectory was identified in a longitudinal study of Holocaust survivors; resilient survivors engaged in creative expression during the holocaust and this creative output persisted throughout their lives (Corley, 2010). In this chapter, resilience and other associated terms, concepts, and models are defined. Psychological, neurobiological, and physiologic factors that promote resilience are outlined, including ways to enhance resilience.

The terms resilience and self-regulation are often employed interchangeably; although resilience is generally regarded as a more specific and narrowly defined term. Self-regulation describes an overarching concept of adaptation throughout life. It describes the ability to adapt to changing environments while sustaining goal directed behaviors. Physiologic self-regulation typically operates outside of conscious awareness, whereas psychological self-regulation is mobilized by a conscious sense of self (Bonanno, 2004). Physiologic and psychological regulation strategies are influenced by dispositional traits. The temperament of an individual will shape the level of reactivity to stimuli and will provoke behaviors that are either withdrawing (inhibitory) or approaching. During development, temperamental disposition shapes self-regulation; however, the need to respond to challenging situations varies amongst individuals. Maturation into adulthood necessitates that more complex strategies are learned and mobilized beyond basic approach or withdrawal impulses.

Resilience refers to individual efforts to achieve good outcomes despite serious threats to adaptation or development (Bonanno, 2004). For example, most children demonstrate incredible resilience throughout development, including acquiring competent skills to meet the demands placed on them. Similarly, most adults are equally able to function despite exposure to traumatic events. When measuring resilience, individuals must first be exposed to adverse events that threaten physiologic and/or psychological stability (Kaye-Tzadok and Davidson-Arad, 2016). They must remain stable across multiple domains of functioning (biological, emotional, educational, social, workplace). Assessing resilience must include a complex interaction of psychosocial and biological factors that are mobilized to resist the negative effects of adversity (Kaye-Tzadok and Davidson-Arad, 2016). Resilient individuals may initially feel overwhelmed during a traumatic event or significant loss, but they are able to function despite feelings of horror or grief. They do not exhibit maladaptive behaviors such as substance abuse, absenteeism, homelessness, or violence. As well, they do not manifest any psychiatric disorders and they are able to maintain good health despite enduring extreme stress (McGloin and Widom, 2001).

Individuals who falter in stressful situations and then recover, or even grow from these experiences later (posttraumatic growth), are not regarded as resilient (Bonanno, 2004). Across research studies, one major limitation when classifying individuals as resilient versus recovered is the inconsistent criteria to determine a history of adversity (Kaye-Tzadok and Davidson-Arad, 2016). For example, grouping individuals after a natural disaster into classifications of resilient, recovered, or suffering PTSD fails to account for prior exposure to traumatic events and the cumulative effects of trauma. An individual who developed in a community that was fraught with poverty, violence, loss, and broken family structures may respond to traumatic events very differently compared to an individual who was raised in a high socio-economic community, with no exposure to violence, and raised in a stable family structure (Hobfoll et al., 2009). Studies demonstrate that less resources, including lack of support from friends

and families, increase the odds that an individual will experience traumatic symptoms, and for a more protracted time, than individuals with more resources. They will not be classified as resilient despite the reality that under less oppressive circumstances they may have manifested resilience (Hobfoll et al., 2009). Despite exposure to cumulative trauma, other factors may promote resilience, such as strength gained from a strong ethnic identity and affiliation with church groups, the arts, or sports (Kaye-Tzadok and Davidson-Arad, 2016). Recent research is now demonstrating that creative engagement is equally important in promoting resilience (McFadden and Basting, 2010). These socio-economic and creative variables directly influence prevalence rates for resilience across studies.

Personality Traits: Hardiness, Grit, and Autotelic Personalities

Hardiness, grit, and autotelic personality are considered inherent traits within an individual; these traits are less driven by psychosocial behaviors. An individual who is described as hardy tends to demonstrate attitudes of commitment and control; they actively seek challenges (Sheard, 2009). They thrive in situations that involve stress and high risk. Hardiness implies that an individual is endowed with superior abilities and is able to meet adversity with success. Although hardy individuals manifest robust physical and psychological strength, they are not immune to illness and disease; however, even when sick they display attitudes and behaviors of control and commitment. Hardy individuals are generally task-oriented and maintain an abiding faith that they can sufficiently manage any situation (Sheard, 2009).

Grit is a concept developed by Angela Duckworth; she observed that long-term goals are often achieved as a consequence of perseverance and passion. Grit is a personality trait that operates beyond the Big Five personality trait of conscientiousness (Duckworth and Quinn, 2009). According to Grit Theory, beyond individual talent and aptitude, persistence and passion strongly predict goal achievement. Even under adversity, individuals who possess grit are more likely to display traits of resilience. Although grit is often examined as a separate factor, cultivating a courageous mindset reinforces efforts to persevere and reduces fear behavior. Courage, like grit, integrates self-reflection and positive beliefs about goal-achieving abilities (Hannah et al., 2007).

According to Csikszentmihalyi (1996), individuals who possess an autotelic personality demonstrate significant resilience under challenging situations. It is a genetically heritable personality trait. Specifically, autotelic individuals possess low neuroticism and high conscientiousness and these traits are amplified in environmental conditions that promote flow-engendering activities (Csikszentmihalyi, 1996). Autotelic individuals have confidence and optimism; they believe that they will not only succeed but also achieve optimal performance states in work and academic settings (Csikszentmihalyi, 1996). They demonstrate personal innovativeness, self-efficacy, and enhanced perceptions of control. Possessing an autotelic personality is also associated with increased health-related quality of life, sense of fulfillment, positive emotions, goal-directedness, and efficient time management (Csikszentmihalyi, 1996). Autotelic personality traits enhance resilience, creative flexibility, and life satisfaction.

Models of Self-regulation and Resilience

There are multiple models that describe self-regulation and resilience. These models offer concepts that capture how an individual may remain resilient despite extreme exposure to adversity (Benight, 2012).

1. Salutogenic Model: Views health and disease on a continuum and reinforces the need to examine protective factors as well as risk factors.
2. Social-Cognitive Theory: A bi-directional theory that includes interactive responses between the environment, person, and behavior (i.e., self-efficacy).
3. Self-Regulation Shift Theory: Builds on the social-cognitive theory and elaborates on dynamic state shifts that provoke destabilization and re-organization.
4. Terror Management Theory: Based on the concept of death-anxiety and ways to manage daily life despite the inevitable reality of death.
5. Transactional Theory of Stress and Coping: The interaction between the environment and a stressful situation reveals physiologic responses, cognitive processes, and coping strategies that are employed to manage stress.
6. Conservation of Resources Theory: This theory examines the losses (finances, employment, home, health, family) that are experienced during stressful situations and how individuals falter or thrive.
7. Social Support Theory: Support from family, friends, community, and/or workplace provides a sense of belonging that buffers the potential loneliness and isolation associated with trauma and loss experiences.
8. Attachment Theory: Early attachment relationships with primary caregivers are internalized and influence a lifetime trajectory of behaviors and states of mind regarding attachment, trauma, and loss experiences.
9. Information Processing Theories of Trauma Responses: Theory that delineates how traumatic responses, both cognitive and emotional processes, involve assimilation and accommodation.
10. Stress-Diathesis Model: Biological genetic predispositions influence vulnerability and resilience under stress.
11. Kindling Theory: A neurobiological theory that describes allostasis and allostatic loading associated with cumulative trauma exposure.

Resilience Factors

Factors that operate as protection from adversity are considered components of resilience. A major resilience factor is early secure attachment experiences. Secure attachment promotes the development of self-regulation skills, positive beliefs about oneself, and intrinsic motivation to succeed in multiple settings (i.e., academic, sport, arts, social) (Moltafet et al., 2018). Children who receive sensitive, attuned parenting from their caregivers internalize optimal emotion regulation coping strategies. Although they are less likely to suffer maltreatment by their caregivers, they may still be raised in adversity, including exposure to domestic violence, family mental illness, substance abuse, incarceration, or the death of a parent. With the early formation of secure attachment, despite adversity, these children are more likely to manifest resilience compared to children classified with insecure attachment (Moltafet et al., 2018). Attachment insecurity is significantly associated with harsh parenting and the persistence of emotional dysregulation in adulthood. Adults with insecure attachment histories have higher risk for disease and mental illness, and they lack the psychological resilience to tolerate pain, including chronic pain (Ogle et al., 2015).

Another major factor that promotes resilience is the perceived ability to access resources. Social support augments adaptation skills, especially under stress. For children, adolescents, and adults, a history of secure attachment promotes the perception that other people are reliable and dependable (Ogle et al., 2015). A sense of self is nurtured in these secure attachment experiences, including a sense of autonomy, self-efficacy, safety, and a positive belief in others (Moltafet et al., 2018). Insecurely attached individuals often draw less comfort from others and do not perceive social support as a resource under stressful situations. A positive perception regarding resource acquisition also promotes a sense of optimism, a trait that enhances resilience. Specifically, optimistic individuals generate positive imagery about the outcome of stressful and traumatic events, which reinforces their resilience (Blackwell et al., 2013).

Creativity is increasingly included as a factor that promotes resilience; in fact, creative engagement is regarded as an expression of resilience (McFadden and Basting, 2010). For example, creative engagement has a neuroprotective effect in older adults. It promotes memory retention and enhances cognitive capacities. Studies on resilience and aging suggest that engaging in creativity slows the natural effects of aging (McFadden and Basting, 2010). In a study on resilient holocaust survivors, creative engagement throughout their lives was a significant protective factor (Corley, 2010). In this study, creative expression had the potential to increase personal and community wellbeing for these survivors. Similarly, creativity was listed as one of the key factors in communities that demonstrated social resilience during and following a major disaster. Remaining creatively engaged enabled the community to effectively manage emergencies and implement new or modified prosocial policies (Kaye-Tzadok and Davidson-Arad, 2016).

Neurological and Physiologic Factors in Resilience

Stress is a natural biological factor in all life forms. Neurophysiological responses to stressful demands may be adaptive or maladaptive; these micro and macro biological system responses determine individual levels of biological resilience. Research studies demonstrate that greater physiologic variance is associated with more resilience, especially when examining the physiologic rate of recovery following a stressor (Razumnikova et al., 2013).

Attachment experiences, both positive and negative, shape resilience or risk responses in adulthood via a complex gene-environment interaction (Gillespie et al., 2009). Attachment experiences mediate polymorphism changes to two key genes, CRHR1 and FKBP5. These genes determine resilient or maladaptive reactivity of the amygdala-hypothalamus-pituitary-adrenal (HPA) axis. As well, increased levels of neuropeptide Y (NPY), oxytocin, and endogenous opioids have been linked with resilience (Gillespie et al., 2009). These neuropeptides are integral components of the HPA axis, as well as the autonomic nervous system and the hippocampus. Individuals with higher levels exhibit more empathic abilities as well as fewer symptoms of stress after exposure to a traumatic event. Even children with high childhood adversity exposure are actually able to enhance cognitive and executive functioning processes when they have elevated levels of NPY and oxytocin (Gillespie et al., 2009). These and other study findings reinforce a direct relationship with optimal genetic heritability. In particular, early caregiving directly influences genetic expression; sensitive (responsive parents) or hostile (unresponsive parents) parenting shape positive or negative childhood gene-environment interactions (van Ryzin et al., 2015).

Posttraumatic Stress and Growth

The term posttraumatic growth was coined to describe a different trajectory in individuals not classified as resilient. It identifies individuals who not only recover from PTSD but also gain a stronger sense of self after recovery. These individuals, who manifest traumatic symptoms following exposure to trauma, are able to attain a positive transformation once the traumatic symptoms abate. Posttraumatic growth factors include an ability to relate to others, a willingness to explore new possibilities, a growing sense of personal strength, transformational spiritual experiences that shift perceptual orientations, and an increased awareness that life is valued and appreciated (Kaye-Tzadok and Davidson-Arad, 2016). Anger also facilitates posttraumatic growth; it can mobilize efforts to change conditions, especially after prolonged exposure to violence. Individuals may endorse one or several of these factors when they describe how they achieved posttraumatic growth (Kaye-Tzadok and Davidson-Arad, 2016). This growth may be sustained throughout a lifetime or be transient. Transient posttraumatic growth is often due to subsequent stressors that occur

throughout the lifespan. Whether transient or persistent, experiencing posttraumatic growth often increases a renewed sense of purpose, meaning, and creativity, regardless of the presence of trauma-related symptoms (Kaye-Tzadok and Davidson-Arad, 2016; Thomson and Jaque, 2018).

Resilience and Creativity

Engaging in creativity and gaining opportunities to master skills, realize talents, and interact in environments that provide social support, all enhance resilience, especially during stressful times (Lee et al., 2016). Children, adolescents, and adults are able to draw upon these positive factors and sustain a sense of autonomy and efficacy. After exposure to a traumatic event, resilience is enhanced when individuals can find meaning in these experiences; in particular, they have an ability to internalize the trauma into a global belief in a world order that contains fairness and an awareness of self-directed and other-directed compassion (Gan et al., 2018). These meaning-making processes enable individuals to find benefits and positive experiences from their exposure to life-threatening events. These experiences can be incorporated into creative activities, and directly or indirectly influence individual creative expression.

Creativity is often associated with talent or giftedness (see Giftedness). Typically, children who are gifted or possess domain-specific talents are often vulnerable to more intense responses to challenges, including more obsessive behaviors while engaging in problem solving tasks. They are more sensitive to environmental stimuli and this is intensified when they are exposed to traumatic events. Their negative reactions increase in adverse childhood environments, which has been associated with a reduction in their ability to realize their creative potential (Knezevic and Ovsenik, 2002). Highly gifted/talented children must acquire psychological skills to manage their emotional and physical intensity as well as ways to regulate anxiety and obsessive behaviors; this is even more relevant for traumatized gifted children. Acquiring these self-regulating skills may enhance creative flexibility and promote more psychological resilience (Gan et al., 2018; Moltafet et al., 2018). As noted by Frank Barron, some highly creative people are extremely vulnerable to mental illness whereas others remain stable and well regulated. These different outcomes may be related to innate resilience factors, or the lack thereof. Despite this variance, studies demonstrate that highly creative individuals tend to recover faster physiologically after a stressor compared to less creative individuals, which suggests that creativity may be a resilience factor (Razumnikova et al., 2013).

The ability to conjure imaginary companions or paracosms (complex imaginary worlds that are elaborated and cultivated over a protracted period of time) is associated with resilience (Aguilar et al., 2017). Imaginary companions provide positive resources including reducing boredom, increasing entertainment, friendship, and social support, especially for children who are placed in foster care after exposure to maltreatment (Aguilar et al., 2017) (see Imagination). Paranormal experiences are also heightened in many maltreated children. Their desire to feel a connection with a power beyond human dimensions and to imagine that they possess supernatural powers provides an antidote to the abuse and neglect they suffer. In all cases, imaginative engagement may provide a sanctuary when exposed to adversity and maltreatment (Corley, 2010).

Another marker of resilience is the ability to intensify or suppress emotional expression in order to optimize responses under stressful conditions (Bonanno et al., 2004). Regulating emotional intensity under stress is also associated with creative expression, especially for individuals working in the performing arts (Thomson and Jaque, 2018). Likewise, emotional responses to traumatic events directly influence the degree of distress as well as positive or negative perceptions about the traumatic event. For example, following the terrorist attacks on September 11th, 2001, even though the dominant feelings of fear, anger, and sadness prevailed, individuals who also displayed positive emotions such as gratitude, love, and hope demonstrated more psychological resilience (Fredrickson, 2004). They were psychologically protected and did not develop anxiety and depressive disorders in the aftermath of this event (Fredrickson, 2004). These findings reinforce the broaden-and-build model of adaptive coping, which posits that the positive emotions influence broader cognitive appraisals from which creative problem solving strategies can be built (Fredrickson, 2004).

Resilience is also evident in the workplace, especially in industries that are typically more turbulent. More resilient industries have greater creative output (Richtner and Lofsten, 2014). It is recommended that managers reinforce the “soft” skills in organizations such as supporting cognitive, emotional, and structural resources; by enhancing these resources resilience and organizational creativity is promoted (Richtner and Lofsten, 2014).

Key factors that promote resilience and creativity are the provision of authentic leadership and encouraging employee psychological capital in the workplace (Marwa and Milner, 2013). The components of psychological capital include efficacy, hope, and resilience; they all positively enhance creative performance. Both authenticity and psychological capital are strongly evident in entrepreneurial groups, especially groups that have the capacity to rebound from adversity and display even more strength, commitment, and resources (Marwa and Milner, 2013). These factors, and in particular, creative engagement, are currently regarded as essential components in all industrial and corporate sustainability efforts. Large organizations are now encouraging creative efforts to promote corporate sustainability and employee psychological capital.

Conclusion

Resilient individuals respond to adversity with a sense of purpose and optimism. In the face of trauma, they sustain cognitive beliefs that solutions can be found and that their efforts have meaning. Ultimately, the concept of resilience is an interactive concept; an

individual assessment must include factors such as genetic inheritance, environmental risks, and lifespan trajectory. The majority of individuals exposed to trauma respond with resilience; however, a much smaller proportion of severely maltreated children (22%) are deemed resilient (McGloin and Widom, 2001). Early traumatic exposure, polyvictimization, cumulative trauma, and biological constraints may erode innate resilience abilities (McGloin and Widom, 2001). In adulthood, these severely maltreated individuals may once again restore their capacity for resilience via increased social support, adequate economic resources, and diminished adversity (Lee et al., 2016).

The relationship between resilience and creativity is strong; in particular, both require cognitive and emotional flexibility. One significant factor that promotes both is experiencing early warm parental care compared to unstructured chaotic parenting (Moltafet et al., 2018). Higher childhood exposure to trauma may not always compromise wellbeing; study findings demonstrate that some individuals may increase achievement and optimize performance as well as derive greater meaning and healing while engaging in the creative process (Thomson and Jaque, 2018). In fact, educational programs that develop creativity, rather than merely allowing creative opportunities, not only enhance creative skills such as solving problems, frustration tolerance, and persistent exploratory behavior, but they also cultivate skills that enhance resilience (Gan et al., 2018; Corley, 2010). This was also evident in a study that investigated resilience in refugees and asylum seekers. Programs that encouraged regular creative engagement enhanced resilience in the refugees and asylum seekers (Gan et al., 2018). In addition, careers that require creative expression promote greater happiness, sense of autonomy, and job satisfaction; all factors that may foster greater resilience in the face of adversity (Bille et al., 2013). Growing empirical evidence now suggests that creativity may be an integral component in resilience.

Theoretical Approaches Linking Rewards and Creativity	448
Meta-Analytic Review of the Reward–Creativity Link	449
Additional Research Examining the Reward–Creativity Link	450
Conclusion	450
References	451
Further Reading	451

The scholarly history of rewards and creativity is long and complicated. Over the past six decades, hundreds of studies have examined the effect of rewards, praise, recognition, salary increases, and prizes, on creativity of diverse types, music, writing, and art, and in diverse contexts, schools and work organizations. Early research often aimed to answer a rather simple question: Do rewards help—or hinder—creativity? Later research has taken a more complex view of the rewards–creativity relationship to consider when and how rewards may differentially affect creativity.

This entry looks back at the controversial and inconsistent findings surrounding the reward–creativity relationship. First, there is a brief overview of two dominant theoretical perspectives traditionally used to explain how rewards may affect performance on creative tasks and examine more contemporary perspectives of the rewards–creativity relationship. Second, the findings of a large-scale meta-analysis that quantitatively synthesized studies that examined the rewards–creativity relationship are presented ([Byron and Khazanchi, 2012](#)). Third, a review of more recent research examining how rewards affect creativity—and whether aspects of the person or situation present important contingencies of this relationship. Finally, a discussion of future research and the possible impacts of not rewarding creativity.

Theoretical Approaches Linking Rewards and Creativity

In earlier research, scholars considering the effects of rewards on creativity generally relied on one of two opposing theoretical perspectives—a behavioral approach or a cognitive approach. Both these broad approaches to motivation will be reviewed and then more contemporary theoretical approaches that consider the role of rewards on creativity will be discussed.

Advanced in the early 20th century by John B. Watson and B.F. Skinner, the behavioral approach suggests that people learn and modify their behavior based on the consequences associated with their behavior. People develop contingent associations between what they do and the consequences of the behavior, and these associations motivate future behavior. In relation to the reward–creativity relationship, scholars who used this approach relied on motivational theories to argue that people respond to the promise of or receipt of rewards with increased creative performance. They argue that people will be more creative when valued rewards are offered or received. According to scholars using this approach, creativity is like any other behavior; it responds to operant conditioning and will be repeated when rewards are positive. Learned industriousness theory ([Eisenberger, 1992](#)) and reinforcement theory ([Skinner, 1968](#)) are examples of theories consistent with the behavioral approach. Scholars using this approach can point to numerous studies that have found that rewards are associated with greater creativity (e.g., [Eisenberger and Rhoades, 2001](#)).

Whereas the behavioral approach suggests that rewards increase creativity, the cognitive approach is often used to suggest that rewards decrease creativity. According to the cognitive approach, intrinsic—rather than extrinsic—motivation is essential to task performance such as creative performance. Extrinsic motivation—such as from the promise or receipt of rewards—undermines intrinsic motivation by suggesting that people no longer have control over what they think and do. They are being driven to act based on what is being rewarded, not what innately drives or interests them. By reducing intrinsic motivation, rewards decrease task performance such as on creative tasks or projects. Cognitive evaluation theory (CET) ([Deci et al., 1975](#); [Deci and Ryan, 1980](#)) and self-determination theory (SDT) ([Deci and Ryan, 1985](#)) are examples of theories consistent with the cognitive approach. Scholars using this approach can point to numerous studies that have found that rewards are associated with decreased creativity (e.g., [Amabile, 1982](#)).

Historically, scholars tended to side with one of these two opposing theoretical approaches. More recently, scholars have been able to rely on contemporary theoretical approaches that consider that rewards can help, harm, or have no effect on creativity—and that aspects of the reward and context determine reward's effect on creativity.

These contemporary perspectives consider rewards as not standing in opposition to intrinsic motivation. [Amabile \(1993\)](#) introduced the notion of “extrinsics in service of intrinsic” (p. 194). She argued that rewards and other forms of extrinsic

motivation can increase intrinsic motivation because people enjoy receiving recognition, praise, and other desired outcomes and such enjoyment can increase the pleasantness of work. In this way, rewards may increase creativity, which is considered highly dependent on intrinsic motivation. Extending this view, [Amabile and Pratt \(2016\)](#) presented a model examining the antecedents of creativity and asserted that extrinsic motivators can synergistically work with intrinsic motivation to increase creativity.

Finding theories to be inadequate at explaining previous research, [Byron and Khazanchi \(2012\)](#) theorized that five mechanisms account for the extent to which rewards either increase or decrease creative performance.

In short, when rewards or their context serve to clarify that creative (rather than routine) output is desired and valued, increase one's perceived competence on the task, associate positive emotion with the task, decrease the association of negative emotion with the task, or increase one's perception of being volitional, rewards are more likely to increase creative performance. In contrast, when rewards or their context fail to clarify creativity as a criterion, decrease one's perceived competence on the task, decrease the association of positive emotion with the task, associate negative emotion with the task, or impose control, rewards are likely to decrease creative performance

([Byron and Khazanchi, 2012](#), p. 811).

Their meta-analytic results—which are summarized below—largely supported these theoretical contentions.

In a refinement of cognitive evaluation theory, [Gagné and Deci \(2005\)](#) similarly argued that rewards—in the right context—can increase intrinsic motivation and thus potentially increase creativity. They proposed that rewards, when administered in an autonomy-supportive climate, can enhance intrinsic motivation. For example, [Ryan et al. \(1983\)](#) provided supporting evidence that research participants offered performance-contingent monetary rewards in an autonomy-supportive context had greater intrinsic motivation than did those participants who were not offered rewards.

In summary, rather than considering rewards as being antithetical to intrinsic motivation and thus creativity, contemporary perspectives offer a more nuanced approach to considering how rewards influence creativity. Such a perspective is in line with the vast majority of empirical evidence, as demonstrated by meta-analytic results ([Byron and Khazanchi, 2012](#)). The next section summarizes this meta-analysis, which sought to answer the question “Do rewards help or hinder creativity?”

Meta-Analytic Review of the Reward–Creativity Link

As mentioned earlier, evidence on the reward–creativity relationship has been mixed: some studies found that rewards increased creative performance and others found that rewards decreased creativity performance. Because of the conflicting results and theoretical perspectives, [Byron and Khazanchi \(2012\)](#) conducted a meta-analysis of existing research that examined the relationship between rewards and creativity. This quantitative synthesis included 60 studies (including 69 independent samples) conducted on a variety of populations (e.g., of varying ages), in a variety of contexts (e.g., work organizations, schools), and using different research designs (i.e., both experimental and nonexperimental designs). Its goal was to explain and resolve the inconsistencies found in prior research. Key findings included considering how reward contingency, reward conditions, and accompanying performance feedback help explain how rewards effect creativity.

First, reward contingency matters. Rewards increase creativity when individuals understand that rewards are contingent on creative performance. The analysis of experimental studies found that creativity-contingent rewards increase creativity and results from the nonexperimental studies concluded there is a small but positive and stable relationship between perceived rewards for creativity and creative performance. In contrast, performance-contingent and completion-contingent rewards did not increase creativity:

When individuals are unclear about the performance criterion or need only participate or complete a task to receive a reward, rewards had almost no effect (i.e., a slightly negative effect that was not significantly different from zero) on creative performance

([Byron and Khazanchi, 2012](#), p. 823).

Second, reward conditions matter. More specifically, creativity-contingent and performance-contingent rewards are more positively related to creativity when participants are given more choice and are less controlled. Rewards offered in conditions that also provide choice—being able to choose the reward or task, for example—benefited creative performance. In contrast, rewards offered in conditions that impose control—offering contracted-for rewards or imposing excessive time constraints, for example—harmed creative performance. It may be that rewards offered along with choice increase task engagement and thus cognitive flexibility whereas rewards offered along with control decreases task engagement and thus cognitive flexibility.

Third, accompanying performance feedback matters. Rewards tended to be more positively related to creativity when individuals were provided with performance feedback that was more positive, specific, task-focused, and contingent on their creative performance. Performance feedback may augment the positive effects of rewards on creativity by, for example, increasing perceived competence and creating positive affective states. People who feel more competent and positive may be more likely to think in a way that promotes creativity—such as having a broad attentional focus and being cognitively flexible.

These results also highlight that the relationship between rewards and creativity is more complex than previously thought. Although the meta-analysis identified important moderators of the rewards–creativity relationship, research since then has further refined what is known about this relationship—and is the subject of the next section.

Additional Research Examining the Reward–Creativity Link

Scholars continue to study the effects of rewards on creativity—to identify boundary conditions, explore intervening mechanisms, and extend effects to different domains (e.g., [Malik et al., 2015](#); [Ng and Yam, 2019](#); [Yoon et al., 2015](#)). This section will review recent theorizing and empirical tests from research scholars published since the [Byron and Khazanchi \(2012\)](#) meta-analysis.

Byron and Khazanchi called on researchers to examine boundary conditions that might affect creative performance. Specifically, they suggested that researchers examine the effects of individual differences in value perceptions of rewards:

... people likely differ in how they perceive and value different types of rewards, and these differences may help determine the effects of rewards. More specifically, whereas some people view monetary rewards as controlling, others view money as a source of freedom ...

Byron and Khazanchi (2012, p. 825).

Some research looked at mediating variables of the rewards–creativity relationship. For example, [Malik et al. \(2015\)](#) and [Yoon et al. \(2015\)](#) both examined the effect of external rewards on creative performance and found positive relationships through other variables. [Malik et al. \(2015\)](#) looked at the effect of external rewards on creative performance through intrinsic motivation and found that this indirect relationship was positive when employees perceived an internal locus of control instead of an external locus of control. [Yoon et al. \(2015\)](#) found a positive relationship between external rewards and creative performance with commitment to creativity as an intervening variable.

Additionally, these authors examined the effects of moderators on the external rewards–creative performance relationship. For example, [Malik et al. \(2015\)](#) found that creative self-efficacy—belief in your own creative skills and abilities—moderated the extrinsic reward–creativity link, such that rewards were more positively related to creativity when people had high (rather than low) creative self-efficacy. When people have high creative self-efficacy, they are driven by their internal belief in their creative abilities and external rewards combine with these beliefs to enhance creativity. In contrast, when people feel that they lack the skills to perform creatively, they likely do not believe that receiving the promised external reward is even possible—and thus rewards fail to motivate creativity.

Another important moderator appears to be the perceived importance of the reward. [Malik et al. \(2015\)](#) and [Yoon et al. \(2015\)](#) found that, for employees who considered the rewards high in importance, rewards were positively related to creativity; for employees who considered the rewards low in importance, rewards were negatively related to creative performance.

Moreover, task complexity moderates the relationship between rewards and creativity. [Hewett and Conway \(2016\)](#) examined the effects of the complexity of tasks on the verbal reward salience–creativity relationship and found that the more complex the task, the less effective the verbal reward in increasing intrinsic motivation (and seemingly creativity). The relationship between reward salience and intrinsic motivation was increased when the verbal reward was given for simpler tasks.

In summary, these findings support assertions that extrinsic motivators positively influence creative performance directly and indirectly especially when the appropriate synergistic conditions are in place. Such findings have important practical implications. For example, when an employee displays low confidence in his or her ability to be creative, a manager may downplay the extrinsic rewards of creativity so as not to lessen the creative output.

Conclusion

Scholars are encouraged to continue exploring the nuances of the reward–creativity relationship. One area for future research concerns the effects of time on the relationships between rewards and creativity. For example, scholars might examine the effects of rewards on creativity over time to determine how the frequency of rewards affects creativity in the long-term. Longitudinal studies may examine whether some reward types are more effective early in a career or learning environment when people are developing creative skills versus when they are more “seasoned.” Many opportunities exist to further understanding of the reward–creativity link.

What would be the impact if creativity went unrewarded? Most simply, without rewards for their creative performance, many artists, musicians, and inventors would struggle to survive—especially early in their careers. Moreover, if creative performance is not rewarded sufficiently in the workplace, employees may withhold their creative behavior because of this seemingly unfair treatment. Research shows that organizational justice impacts employee attitudes (i.e., job satisfaction, organizational trust, organizational commitment), counter-productive work behaviors, organization citizenship behaviors, and overall task performance ([Colquitt et al., 2013](#)). In essence, not rewarding creative performance violates norms of society, particularly in Western cultures.

Whereas early theory and research was focused on *whether* rewards increase or decrease creativity, more recent theory and research is focused on *how and when* rewards increase or decrease creativity. Moving away from earlier simplistic views of rewards,

it is clear that the relationship between and creativity is complex relationship. Hopefully future research will help further unravel rewards' effects on creativity.

Introduction

When you are insane you are busy being insane – all the time ... When I was crazy that was *all* I was
 Sylvia Plath, cited in *Sounds from the Bell Jar*, Claridge, Pryor and Watkins, 1998, p. 4.

This entry introduces the construct of schizotypy and examines whether schizotypy confers a creative advantage, and if so, why. While schizophrenia has been associated with impaired functioning and with low levels of creativity, high levels of creativity have been observed amongst people who score highly on subclinical measures of schizotypy, and amongst non-diagnosed relatives of people who have been diagnosed with schizophrenia (Sass and Schulberg, 2000–2001). This led to suggestions that cognitive mechanisms underpinning aspects of schizophrenia may also facilitate creativity, but only when expressed at mild to moderate levels and/or in interaction with ‘protective factors’ that enable healthy functioning. However, both schizophrenia and schizotypy are multi-dimensional and complex constructs, as is creativity, and it will be argued that not all aspects of schizotypy are useful for creativity, and that not all types or subcomponents of creativity are potentially related to it. Further, since creativity has also been associated with healthy, efficient and adaptive functioning, the apparent paradox that it may also be associated with schizotypy will be explored.

The definition of creativity will follow the most commonly accepted version, as: a process through which a novel and useful or adaptive product or performance ensues. Creativity is considered to be multi-dimensional and to consist of numerous potential processes (neurocognitive, affective, behavioural), numerous potential domains (e.g., everyday life, the arts, sciences, intrapersonal) and multiple stages, including processes that are generative or explorative and enable novelty and processes that enable the selection, evaluation and development of material that renders a product or performance adaptive.

What Is Schizotypy?

The term schizotypy is used to describe a heterogeneous mix of experiences, expressed at a subclinical level, that are analogous to those that categorise schizophrenia (Mason and Claridge, 2015). These include experiences analogous with the positive, negative and disorganised symptoms of schizophrenia.

The positive symptoms of schizophrenia consist of hallucinations and delusions, but in schizotypy are expressed in forms more commonly experienced in everyday life, such as: 'magical thinking', including a belief that telepathy (mind-to-mind communication without the use of the five senses) is possible; pseudo-hallucinations, such as having had a 'sense of presence' (perhaps evil and foreboding) despite no person being physically present; perceptual aberrations, such as seeing shapes and colours in the dark when nothing is there; and cognitive aberrations, for example, one's thoughts seeming to be so vivid that one can almost hear them (analogous with the most common form of hallucination in diagnoses of schizophrenia – hearing voices).

The negative symptoms of schizophrenia are characterised by an absence of pleasure and engagement with aspects of everyday life (avolition, anhedonia, alogia). In schizotypy, such experiences include physical anhedonia, gaining little or no pleasure from the senses or from experiences that are usually deemed to be pleasurable (such as enjoying the taste of new foods or dancing), and social anhedonia, preferring solitary activities to spending time with others and not feeling close to other people.

In schizophrenia, cognitive disorganisation refers to problems with executive function, such as sustained attention, and is characterised by cognitive derailment and 'word salad' (where speech appears to be tangential with an unusual logical structure and choice of words). In schizotypy, cognitive disorganisation is expressed in a milder form, for example, as being easily distracted by daydreams, or feeling overwhelmed when walking into a crowded, busy room.

Some measures of schizotypy also include a fourth, and more contested dimension, called impulsive non-conformity. This construct is thought to overlap with psychoticism and includes thoughts and behaviours that are impulsive or antisocial, such as feeling an impulse to do something harmful or shocking or wishing other people to be afraid of oneself. This construct also overlaps with mood lability and hypomania.

Clearly then, schizotypy is a multi-dimensional construct, and it is important to note that these four dimensions do not share the same associations with cognitive and wellbeing measures. For example, the positive dimension correlates less consistently with indices of poor executive functioning and wellbeing, and in some research is associated with high levels of wellbeing, unlike the negative and disorganised symptoms.

While schizotypy is typically modelled as a personality trait, where people vary on a continuum according to how 'schizotypal' they are, there is debate concerning its health implications (Mohr and Claridge, 2015). This debate revolves around evaluating and interpreting the empirical support for two competing models of schizotypy – the 'fully dimensional' and 'quasi dimensional' models. Essentially, these models differ in the extent to which schizotypy is thought to be on a continuum with schizophrenia. The fully dimensional model considers schizotypy to be neutral in terms of its health implications, and to be a personality trait, albeit one where high levels may predispose people to psychosis in the presence of risk factors (e.g. stressful life events, a lack of social support and appraising schizotypal experiences as being distressing).

Importantly, in the fully dimensional model, trait level expressions of schizotypy in a healthy population are on a continuum with symptoms on the schizophrenic spectrum, with no clear dividing line between 'normal' and 'abnormal' experiences. It is important to note that this model allows for the possibility that schizotypal experiences may be adaptive, for example heightening creativity or a sense of living a meaningful life (eudaimonic happiness), and as such supports the construct of 'healthy schizotypy'. Alternatively, the quasi dimensional model considers schizotypy to be a 'forme fruste', a risk factor for psychosis, that is indicative of dysfunction (wellbeing, social, cognitive), albeit sometimes expressed in mild and manageable forms in daily life.

The quasi dimensional model is categorical, where, rather than everyone being on a schizotypal dimension, some people are schizotypal and others are not, and the estimated 10% of the general population who are schizotypal are thought to be at risk for developing psychosis. It is for this 10% of individuals where a 'dimension' lies in the model, where there are variations in the severity of the schizotypal experiences.

Schizotypy, then, is not only a heterogeneous construct, but can be understood in different ways, as a risk factor for psychosis, or as a personality trait with potentially adaptive outcomes. These models impact the interpretation of any relationship between creativity and schizotypy. For example, at a simplistic level, a relationship could either be interpreted as supporting a link between creativity and 'mental illness' or as illustrating adaptive and normative expressions of schizotypy. Further, research examining the relationships between creative functioning, schizotypy and wellbeing can potentially provide support for either of these models, and this issue will be returned to later in this entry.

Just as there are diverse operational definitions and measures of creativity, there are a range of schizotypy questionnaires in the literature and the differential use of these may obfuscate relationships. For example, different schizotypy questionnaires vary in the severity of items, some including more 'symptom-like' experiences, with implications for their correlations with both wellbeing and creativity measures. Questionnaires that assess positive schizotypy with 'milder' experiences include items such as 'sometimes seeing shapes and forms in the dark' and having 'rushes of insights', rather than items such as 'feeling like my body is rotting inside' and being 'hyperaware of and unable to shut out sounds and sights', items that are both more negative and involve lack of control.

Schizotypy questionnaires are also sensitive to response biases. For example, participants are more likely to report having had schizotypal experiences if the questionnaire is presented as being relevant to creativity, compared to being presented as a clinical measure. As such, it can be difficult to compare schizotypal findings and levels across studies. Finally, issues arise in the literature due to unmeasured interacting variables and curvilinear patterns, where, for example, moderate levels of schizotypy might enhance creativity, while high levels may inhibit it, or aspects of it. The caveats discussed in this paragraph, in addition to the multidimensional nature of both creativity and schizotypy, must be borne in mind when examining the empirical support for a link between schizotypy and creativity.

Might Schizotypy Confer a Creative Advantage?

Literature reviews and meta-analyses do support a link between creativity and schizotypy. However, the relationship appears to hold for certain dimensions of schizotypy and types of creativity only. For example, in the first meta-analysis of this field, including 45 studies, [Acar and Sen \(2013\)](#) reported a significant but small positive relationship between the positive-impulsive dimensions of schizotypy (which they combined) and creativity measures (which included a broad range, such as divergent thinking, creative personality and artistic involvement). However, negative and disorganised symptoms (combined) appeared to inhibit creativity. Further, literature reviews have reported that the most robust and consistent relationship is between positive schizotypy and artistic involvement (and to a lesser extent with the making of remote cognitive associations) ([Mason and Claridge, 2015](#)). As such, the relationship between creativity and schizotypy may be specific, where particular dimensions of schizotypy relate only to certain types of creativity (or to certain stages of the creative process). This specificity will be considered below, examining the relationships between each dimension of schizotypy and creativity.

Positive Schizotypy

The positive dimension of schizotypy, and unusual experiences more generally, has been most frequently studied in relation to creativity. This may be due to descriptions of unusual experiences in the creative process by famous artists and scientists, many of which are well-known, and have been linked with ‘moments of inspiration’, experiences of ‘the muse’, or intense absorption in the creative process. Examples include the hypnagogic pseudo-hallucination in which the 19th Century theoretical chemist August Kekulé reported seeing patterns ‘gambolling before his eyes’ in which an ouroboros could be discerned, suggesting to him that the structure of benzene, for which he was searching, was circular. Other examples include the reverie of Samuel Taylor Coleridge in which he reported ‘images rising up’, producing without conscious effort the poem *Kubla Kahn*, and the hallucinatory experience of Edvard Munch, whom, whilst walking with friends by a ‘blue black fjord’ reported that a “great scream pierced through nature”, expressed in his most famous painting ([Holt, 2012](#)).

Less often discussed are the experiences of sensed presence and dissociation that have often been reported by creative writers, as illustrated by William Thackeray, who wrote: “I have been surprised at the observations made by some of my characters. It seems as if an occult power was moving the pen. The personage does or says something, and I ask, how the dickens did he come to think of that?” ([Holt, 2012](#)) (See Writing).

A more common form of dissociation reported in the creative process, accompanies intense involvement and attentional focus, often with a loss of awareness of self, boundaries, time and place. This state is akin to the flow state and is described clearly by Marion Milner in her book *On Not Being Able to Paint* (1950, p. 152) when absorbed in painting: “The process always seems to be accompanied by a feeling that the ordinary sense of self had temporarily disappeared, there had been a kind of blanking out of ordinary consciousness; even the awareness of blanking out had gone, so that it was only afterwards when I had returned to ordinary consciousness that I remembered that there had been this phase of complete lack of self-consciousness”.

Clearly then, states characterised by pseudo-hallucinations and dissociation, core features of positive schizotypy, have been implicated in the creative process in numerous ways, both inspiring and accompanying creative production. Nevertheless, such anecdotal reports might be distorted by reporting biases, for example, being misremembered or exaggerated, perhaps to reinforce an image of ‘creative genius’ ([Sass and Shuldberg, 2000–2001](#)).

A number of empirical studies have compared levels of schizotypy amongst artists, scientists and ‘non-artist’ groups (or with normative schizotypy scores) ([Holt, 2018](#)). Positive schizotypy has consistently been found to be significantly higher amongst artists (including poets, visual artists and musicians) compared with control and scientist groups. For example, [Rawlings and Locarnini \(2008\)](#) compared the schizotypy levels of professional artists with scientists. Artists scored significantly higher than scientists on positive schizotypy. The authors further reported that this relationship appeared to be mediated by the ability to make more original and idiosyncratic responses on a word association test. Indeed, much of the research on positive schizotypy and creativity has been based on associative models, where it is hypothesised that they share cognitive features (such as ‘over-inclusive thinking’) that enable remote associations to enter awareness, a process that might both facilitate novel combinations (required for creativity) and irrelevant associations that may be apophenic (the apprehension of aberrant meaning) and lead to delusional ideation in the context of schizotypy. The findings of [Rawlings and Locarnini \(2008\)](#) supported previous studies finding a link between positive schizotypy and idiosyncratic associations, collectively providing some support for this hypothesis.

However, the relationships between positive schizotypy and other measures of creativity, such as creative personality and divergent thinking are less clear, with conflicting outcomes. This may reflect the characteristics or limitations of the measures involved, as well as the inconsistent use of measures across studies, or, as indicated by [Acar and Sen’s \(2013\)](#) meta-analysis, any effect may be a small and unlikely to be consistently detected in studies with small sample sizes. Different creativity measures operationally define creativity in different ways, ways that may differentially relate to schizotypy. For example, the most commonly used measure of creative personality may be confounded with traits required to be a ‘successful’, professional ‘creative’ since it was validated with high achieving samples (and includes items such as self-confident, egotistical, dominant). As such, this scale may not effectively measure the thoughts, feelings and behaviours associated with ‘everyday’ creativity. Divergent thinking tasks require one to select and develop one’s most original ideas rather than simply ‘free associating’ and responding immediately. As such they may require

more sustained attention and evaluative cognition than word association tasks. Currently, the clearest research outcomes are that positive schizotypy is associated with particular domains of creativity (the arts) and may facilitate the generation of 'novelty' in the creative process (at least in terms of making original word associations).

Impulsive Nonconformity

At a behavioural level, taking risks and breaking norms has clear overlaps with creative personality traits. Indeed, impulsive and 'antisocial' traits were observed in the development of early creative personality scales, where it was noted that successful 'creatives' often described themselves as hostile, impulsive, norm-doubting and as not being commonplace. Like positive schizotypy (but less consistently), impulsive non-conformity has been found to be higher amongst artists than the general population (Holt, 2018). It has been argued that this may be due to a willingness to question common values and perceptions, to deviate from norms and conventions, and to express potentially shocking ideas; behaviors that find useful expression through the arts. Interestingly, research suggests that impulsive nonconformity may facilitate the making of remote associations by disinhibiting taboo, antisocial or idiosyncratic associations. Such disinhibition would widen the availability of original associations. Responses on word association tests have been found to be particularly original when participants have scored highly on both positive and impulsive schizotypy traits, and schizotypy has predicted making word associations that are both more original and socially 'taboo'. This suggests that schizotypy might be associated with originality partly through a willingness to explore 'socially undesirable' responses.

Cognitive Disorganisation

Cognitive disorganisation forms mixed, often null, outcomes with measures of creativity and appears not to be useful for creative functioning, and, as suggested by the small negative effect in Acar and Sen's (2013) meta-analysis, may even impair it. Since it has been related to distractibility, social anxiety, low self-efficacy, emotional confusion and reduced conscientiousness, perhaps this is not surprising, since it may limit creative achievement through reduced determination, focus and confidence, traits that identify individuals on measures of creative personality. Cognitive disorganisation has clearer links with cognitive 'dysfunction' than positive and impulsive schizotypy, being associated with poor executive control and reduced semantic fluency, suggesting that it is antithetical to creativity at both a trait and cognitive level. However, some (inconsistent) studies have observed higher levels of cognitive disorganization amongst artists, for example musicians (Rawlings and Locarnini, 2008). This may be due to response biases, type one errors, some unidentified factor of cognitive disorganisation that promotes creativity, or perhaps to stressors associated with working as a professional artist.

Negative Schizotypy

With its emphasis on social anhedonia, it has been suggested that negative symptoms could make solitary work easier to bear, withdrawing to focus on creative endeavours. However, most research finds that negative symptoms inhibit or play no role in creativity, supporting Acar and Sen's (2013) meta-analysis. For example, negative schizotypy is not inflated amongst artistic samples. Further, in a sample of artists it inversely predicted experiences in everyday life that often co-occur with creativity, including the flow state and positive affect. Rather, it was associated with moments of low self-esteem, tension and apathy (Holt, 2018). In other research negative symptoms have been associated with lower levels of openness-to-experience, reduced verbal fluency and executive dysfunction, all of which are important to creativity. Potentially, then, negative schizotypy may inhibit creativity in numerous ways, due to a lack of: excitement and sensation seeking (not exploring ideas and experiences); social support (withdrawing from others, who might help or inspire them); and less frequent positive moods in everyday life, which facilitate original ideation.

Summary

Only certain dimensions of schizotypy (the positive dimensions) appear to be linked with creativity – and further, this is limited to particular domains and stages of the creative process: the discovery of new and original ideas; and absorption in the creative process. This does not support a strong and direct link between the schizophrenic spectrum and creativity, but rather suggests that any link is partial and specific, and related to dimensions of schizotypy that are least associated with cognitive and social impairment and low levels of wellbeing. It is of interest that artistic samples have displayed schizotypal profiles characterised by positive but not negative dimensions of schizotypy. However, it is not clear how positive schizotypy might be useful to creativity, whether, for example, schizotypy might lead to creative insights or to autotelic states, such as the flow state that motivate engagement with the creative process. It is to such considerations that this entry now turns.

Why Might Creativity and Schizotypy Be Related?

Different approaches have been taken in attempts to understand why creativity and schizotypy might be related, including cognitive, trait, state, and affective and motivational approaches. These models not only have implications for understanding the potential mechanisms at play, but also whether links are direct or indirect, and the direction of any causal explanation. While it is commonly

assumed that there is something about schizotypy that leads to creativity, for example through 'loose cognitive associations' that facilitate novelty, not all explanations follow this causal trajectory. For example, some motivational models suggest that schizotypal individuals might engage with the arts as a way to express and explore their unusual experiences. Further, it has been argued that schizotypy and creativity might be indirectly related through some shared third variable, such as openness to experience. Such issues will be briefly explored in the following sections. Most of this work has focused on the positive dimension of schizotypy, and therefore this review will do likewise, although it is of note that some models argue that negative schizotypy works in the opposite direction, supporting a bi-directional model of their relative impact on creativity.

Cognitive Explanations

Aspects of cognition which are thought to lead to cognitive impairment in the context of schizophrenia have also been linked to both schizotypy and creativity. These include reduced top down control, cognitive disinhibition and widened attentional capacity. Much theoretical and empirical work has focused on cognitive disinhibition and the idea that there may be a continuum of 'cognitive looseness', ranging from functional fixity to fluid associative cognition (with increased access to remote associations) to increasingly psychopathological and disorganised ideation (being bombarded by irrelevant cognitive content). Such models draw upon early associative models of creativity, where creativity was defined as the making of relevant but remote associations. Hans Eysenck suggested that latent disinhibition might be the mechanism that enables remote associations.

Latent inhibition refers to the effective filtering of irrelevant information from attention, an unconscious process that reduces the load on working memory, and is required for effective functioning in everyday life. Tests of latent inhibition expose participants to an irrelevant stimulus and inhibition of this stimulus is thought to occur when it is subsequently ignored (filtered out of attention due to its 'irrelevant' status). Latent disinhibition, where the stimulus is not subsequently ignored, has been found amongst those scoring highly on both the positive and impulsive dimensions of schizotypy, whereas latent inhibition has been associated with negative schizotypy, although there are discrepancies in the literature.

Several studies have explored whether latent disinhibition is associated with creativity. Carson et al. (2003), for example, reported that psychology undergraduates with high levels of creative achievement were more likely to attend to the irrelevant stimulus in the testing phase, demonstrating latent disinhibition. This effect has been replicated with professional actors, but again, measures of divergent thinking and creative personality have had mixed success as predictors. The relationship may be complex and depend upon factors such as level of schizotypy, intelligence, gender, and cognitive load of the masking task. However, latent inhibition tasks might not be best suited to assessing the potential tendency of creative individuals to access states characterised by cognitive disinhibition, since research suggests that creative people may be able to shift between defocused and focused attentional states according to task demands – being 'ambicognitive' – able to focus on intelligence tasks and 'daydream' on creativity tasks. Hence, masking tasks that are playful and encourage disinhibition (rather than encouraging focused attention) might achieve stronger results.

Overall, while cognitive explanations are theoretically compelling, the link between them and both schizotypy and creativity has limited support and requires more careful research to determine the conditions under which any relationship might be reliably replicated. Research on shared neurological correlates might also deepen understanding, for example, both schizotypy and creative idea generation may share reduced deactivation of the right prefrontal cortex, which is involved in numerous complex states such as episodic memory retrieval, mental imagery and self-consciousness (Fink et al., 2014). Deactivation of the prefrontal cortex has been correlated with focused attention (suppressing unnecessary stimuli), and reduced deactivation with altered states, such as sleep and mystical experiences. As such, this suggests that both schizotypy and idea generation may both be underpinned by mechanisms that enable defocused attention and more stimuli entering attention. Further research on additional cognitive features and mechanisms that might link creativity and schizotypy would be useful, for example, vivid internal imagery, since daydreaming, characterised by focusing on internal stimuli (typified by visual imagery, memories, fantasies of possible events and internal monologues) has been found to be predictive of both schizotypy and creativity.

Motivational and Affective Explanations

Affect and motivation might better explain the relationship between positive schizotypy and creativity. Positive schizotypy has been found to significantly and positively correlate with cyclothymia and hypomania, leading to propositions that heightened experiences of positive affect and motivation amongst people who score highly on positive schizotypy might drive the creative process. This is supported by research suggesting that motivation and moderate positive moods (especially positive and 'approach' emotions, such as joy) facilitate creativity; findings which have been explained by dopaminergic models, which are also implicated in schizotypy. Baas et al. (2019) linked positive schizotypy (and hypomania) with 'approach emotions' (and negative schizotypy with the avoidance system) and found that this cluster (positive schizotypy and hypomania) significantly predicted divergent thinking.

Further research has tracked the moods, and time spent making art, of artists using the experience sampling method (Holt, 2018). After making art artists reported feeling happier and had higher levels of self-esteem. Artists who scored highly on positive schizotypy also reported making art more often and had a significantly greater increase in positive affect after making art than those who scored lower on positive schizotypy. This aligns with Baas et al.'s 'approach-avoidance motivation' model and suggests that positive schizotypy might increase sensitivity to reward and being motivated to seek it out (the reward of feeling good after art

making in this case). Baas et al. also suggested that the approach system motivates people to seek out novelty, which may increase ideas and experiences available to make remote associations. There are clearly conceptual overlaps with the cognitive models discussed above, since positive affect also increases the making of remote associations, and further theoretical work to link neurocognitive and affective/neurochemical approaches would be useful.

Overall, evidence supports variability in affect and motivation as an explanatory variable in the relationship between positive schizotypy and creativity, however, the causal nature of this requires further elucidation. While it is possible that sensitivity to reward drives the creative process, and that positive affect increases novel associations, additional interpretations could be made. For example, high levels of motivation to create could lead to sleep deprivation, which is linked with unusual experiences. Alternatively, having unusual experiences itself may motivate people to express these through the arts, since they enable subjective, idiosyncratic exploration and representation, which may lead to increased wellbeing through catharsis. Finally, there may be a shared third variable that leads to creativity/artistic involvement, positive schizotypy and moments of rewarding positive affect, such as openness-to-experience.

Personality Explanations

Openness-to-experience has been proposed as a potential third variable that might predict behaviour, affect and cognition associated with aspects of both schizotypy and creativity. As a trait, openness-to-experience involves an openness to and exploration of novel and unconventional ideas, sensation seeking and curiosity about both 'inner and outer worlds'.

Openness-to-experience is a strong predictor of creativity and has also been found to correlate with positive schizotypy (and negatively with negative schizotypy). In an interesting study, Miller and Tal (2007) reported that openness-to-experience explained the variance between creativity and schizotypy and argued that personality models were more useful than models of psychopathology to explain their association. Curiosity may lead to the exploration of unusual perspectives and ideas and openness to these (e.g. paranormal beliefs), as well as asking questions and considering novel approaches which may facilitate creativity. Seeking out new experiences may also be linked with both creativity and schizotypy, for example meditation or drug-induced experiences. That the taking of psychotropic drugs has been reported to be higher amongst professional artists and those who score highly on positive schizotypy, supports the hypothesis that positive schizotypy amongst artists may be a by-product of experience-seeking (See Drugs and Personality: Openness).

State Explanations

Both positive schizotypy and creativity can involve dissociative states (the temporary alteration or separation of mental processes that are normally experienced as integrated). Indeed, positive schizotypy might facilitate normative dissociative states such as daydreams and the flow state that might foster engagement in the creative process. Mihaly Csikszentmihalyi observed that the flow state was a common component of the creative process, described by eminent artists and scientists whom he interviewed. This state involved a loss of self-awareness in moments of intense concentration.

Nelson and Rawlings (2010) found that amongst a sample of artists, positive schizotypy predicted reporting moments of normative dissociation in the creative process, including creative experience being 'distinct' from everyday experience (e.g. a loss of self-awareness) and entering states of deep absorption. They suggested that positive schizotypy may facilitate the 'flow state' but did not directly test this. Nevertheless, this has been supported by further research where positive schizotypy predicted experiencing the flow state in daily life in a sample of artists (Holt, 2018). Interestingly, in this study negative schizotypy was negatively associated with the flow state, and also with avolition and negative affect, supporting the idea that positive and negative dimensions of schizotypy operate in opposing directions in relation to creative functioning (in the arts at least) (See Flow).

In summary, despite limited research exploring this topic, there is evidence to support the idea that positive schizotypy may be expressed in a particular way in creative samples, being associated with adaptive absorbed attentional states. Yet, in undergraduate and clinical samples, positive schizotypy has been associated with 'unhealthy' forms of dissociation (e.g. depersonalisation and derealisation). Further research could explore types of dissociation that might mediate a link between positive schizotypy and creativity, and even their developmental pathways, since different pathways to dissociative experiences have been proposed, through experiences of childhood trauma (depersonalisation and derealisation) versus encouragement to engage in creative and imaginative play (absorption).

Summary

There may be multiple pathways between creativity and positive schizotypy, where it can facilitate novel ideation, drive the creative process through sensitivity to approach emotions, or increased access to autotelic states such as the flow state. Although evidence for these links needs to be improved, and causality better understood, aspects of the above models could potentially be synthesised into a broader systems model that accommodates cognitive, affective, motivation, trait and state factors. Indeed, the different mechanisms reviewed may be forms of 'openness' or 'approach systems' at different levels: behavioural (sensation seeking); affective and motivational (positive affect and flow); and cognitive (loose playful associations).

Social factors need also to be considered. For example, research takes place as a social activity, and may be limited by demand characteristics, including response biases, where, for example, it may be more acceptable amongst artistic populations to endorse

statements that are unusual or taboo, which may explain inflated schizotypy scores. Social perspectives are also a reminder that it is convention and gatekeeping that decides both what is 'schizotypal' and what is 'creative' (Sass and Shuldborg, 2000–2001). It is possible that understanding of some of the issues at hand would benefit from expanding social constructions of what is 'normal' everyday experience versus 'schizotypal' experience.

Dual Factor Models

Even at its most simple level the creative process is commonly modelled as being comprised of multiple states, states that require expansion versus constriction, both the broadening of cognitive associations to generate new ideas and the inhibition and focus required to select the most appropriate ideas and develop them into a creative product or performance. In order to engage with both of these stages creative individuals may need more than inflated positive and impulsive schizotypy scores. Creativity is not just associated with aspects of schizotypy, but with indices of wellbeing and executive functioning, such as happiness, intelligence and working memory. Noting this complexity, dual-factor models propose that creativity is associated with both traits indicative of a predisposition to psychopathology (such as schizotypy) and 'protective' factors (e.g., resilience, intelligence, executive functioning, cognitive flexibility).

This is not a new idea. In the 1960s Frank Barron observed that highly creative individuals scored highly on indices of both psychopathology and wellbeing (e.g. ego strength), leading him to coin the term 'controllable oddness' to describe the harnessing of novel and idiosyncratic perspectives to an applied and adaptive end. A more recent approach, suggested early on by Ruth Richards, and later by Shelly Carson, proposed a 'shared vulnerabilities model' where, for example, vulnerability to cognitive disinhibition interacts with protective factors such as intelligence and working memory capacity to enable creativity (See Compensatory Advantage).

Indeed, some research supports this, where high creativity scores have been found amongst participants who score highly on both psychosis-proneness and resilience; latent disinhibition and intelligence; idiosyncratic word associations plus efficient executive functioning (the ability to inhibit responses when required); overinclusive thinking and cognitive inhibition; and schizotypy and both divergent and convergent cognition. Cognitive flexibility may enable high creatives to shift along 'associative hierarchies' according to task demands, being both 'schizotypal' and 'non-schizotypal' as required.

In addition to the presence of protective factors, however, the absence of risk factors may be equally important. As discussed earlier, the relationship between creativity and schizotypy is complex, since positive schizotypy may increase and negative schizotypy decrease the expansion and the generation of ideas, for example. As such the absence of negative and disorganised schizotypy might be required for creative functioning. Research has identified different schizotypal profiles: healthy schizotypes (who only score highly on positive dimensions); high schizotypes (who score highly on positive, negative and disorganised symptoms); low schizotypes (who have low scores on all dimensions); and negative schizotypes (who score highly only on negative schizotypy). Of the two profiles characterised by positive schizotypy it is the so-called healthy schizotypes alone who have scored highly on levels of wellbeing. The research described in this chapter has often conflated these two profiles, and future work could profitably examine creativity amongst 'healthy schizotypes'.

In summary, research and theory supports Barron's notion of 'controllable oddness'. However, how exactly this works, and which protective factors are required, is not clear. For example, this may purely be a function of curvilinear patterns, where moderate levels of positive schizotypy facilitate novel ideation without impairing cognitive function. Alternatively, high levels of positive schizotypy might still lead to creativity, as long as protective factors are present, factors which are orthogonal to schizotypy but interact with its expression. More understanding of how positive schizotypy is phenomenologically expressed in creativity would be useful to understand these issues, since unusual experiences may be of a different type than those associated with psychopathology (e.g. normative dissociation and 'rushes of ideas' rather than paranoid ideation and apophenia).

Conclusion

There appear to be multiple links between creativity and schizotypy that deserve further exploration, both empirical and theoretical: neurocognitive, affective, state and trait. Positive schizotypy may facilitate both: novel ideation that may inspire the creative process; and states of positive affect and flow that may drive the process. Further research is required to articulate the precise mechanisms by which this may occur and validate such causal hypotheses. However, the research on creativity and schizotypy is enmeshed with problems with the operational definitions of both constructs. For example, much of the research links positive schizotypy with artistic involvement and the making of remote associations. However, involvement with the arts does not require creativity in that domain, and idiosyncratic thoughts may be neither useful nor adaptive. As such research might profitably explore positive schizotypy in relation to creativity tasks that better reflect the complexity of the construct.

Perhaps a more thorny issue relates to the implications of the positive schizotypy-creativity link for conceptualisations of mental health and normative conscious experience. Rather than framing these links as evidence for a link between creativity and mental illness, for example, an alternative rhetoric draws upon the fully dimensional model of schizotypy. This perspective would model positive schizotypal experiences as normative that, under the right parameters, can lead to creativity and wellbeing. With this approach come potential clinical implications, where, drawing on the increasing evidence of the mental health benefits of engagement with the arts (including poetry, journaling, painting, crafting, coloring, singing) – artistic interventions might be developed to

help people with unhealthy experiences of schizotypy to self-regulate, manage, express, interpret and control these experiences, as well as experience joy and flow through engaging with the arts.

Creativity in Science

When many people are asked about creative activities, they inevitably conjure up artistic creations: poems, novels, photographs, plays, sculptures, songs, etc. And if asked if they are creative they often say no precisely because they are not involved in such activities. Yet creativity is hardly the sole province of art. Creative thought and behavior happen in any and all domains of life, from cooking, building, and surviving to science. Indeed, science ranks up there with art as an occupation that would not exist if it were not for creative ideas and creative solutions to problems.

Although science requires as much creativity as art, its form and expression are somewhat different. Whereas artistic creations may involve often personal visions and emotional reactions to one's world, scientific creations involve ways to test our ideas about how the world works—and the world is not just the physical world, but rather the biological and social worlds as well. Creative insight is a must in science.

How is creativity in science manifested? The simple answer is nearly every aspect of science—from grand theory building to minute technical solutions to lab problems—involves creative thought. After all, as many other writers in this *Encyclopedia* have pointed out, creative thought and behavior must be both novel/original and meaningful/useful/adaptive. Therefore, **scientific creativity** is simply any thought or behavior in science that is both novel and meaningful to others; with creative thought or behavior in science being manifested throughout the scientific process, from theory construction and hypothesis formation, research and study design, to publication and communication of results. New and important discoveries in science come about often because of creative ideas and hunches of the scientists behind them. Of the thousands of new scientific articles being published world-wide each month, the vast majority of them are published precisely because they report some original finding, technique, or discovery. As Simonton argues, creativity in science is less and less manifested in the “lone genius” and more and more in the scientific team or laboratory, and indeed the lone scientific genius who creates new disciplines and revolutions may be over. To be sure, creativity in science occurs both at the individual and the group level. Either way, it is clear that science and creativity go hand in hand. What does the scientific literature have to say about the nature of scientific creativity?

The Science of Scientific Creativity

There is a newly established discipline that is well-situated to explore and uncover the nature of scientific creativity and that discipline is the psychology of science. The **psychology of science** is the scientific study of both implicit and explicit scientific thought and behavior. As Feist argued in *The Psychology of Science and the Origins of the Scientific Mind*, psychology is the only study of science that examines scientific thought and behavior from an empirical and even experimental perspective. Hence, the psychology of science is well-situated to uncover the nature of scientific creativity. The psychology of science empirically focused on at least

This article is an update of G.J. Feist, Creativity in Science, Editor(s): Mark A. Runco, Steven R. Pritzker, *Encyclopedia of Creativity* (Second Edition), Academic Press, 2011, Pages 296–302.

four major elements of creativity in science: neural complexity, development of scientific talent and achievement, personality traits of highly creative scientists, and creative cognition in science.

Neural Complexity

One of the more exciting recent perspectives on creativity is the neuroscientific perspective. Each year, our understanding deepens as to the neural foundations of creative thought, including scientific creativity. One general conclusion from this research is the brains of creative people are often marked by more complex and more highly interconnected neural circuits than those of less creative people. That is, highly creative people appear to have greater neural connectivity between all major associative regions of the brain. Such a finding would be consistent with one of their most consistent and robust abilities in the creativity literature, namely, that creative people generate many more ideas, and the ideas they generate are looser and more remote in their associations. They are more cognitively fluent. This may be so because of a brain that simply has more connections, making rich associations more likely. Idea generation is as much about making connections as anything. Indeed, the frontal lobes themselves may well be especially important in this overall greater neural connectivity given the frontal lobes do more to connect various regions of the brain than any other lobe.

The neurological condition known as synesthesia appears to be related to creative associations. Synesthesia occurs when two or more of a person's sensory modalities (taste, smell, touch, seeing, and hearing) get mixed. For example, a synesthete may experience colors when perceiving numbers or smell words. More than a few of our most creative scientists, inventors have had synesthesia, including Richard Feynman, Daniel Tammet, and Nikola Tesla. One compelling theory for synesthesia put forth by Ramachandran and Hubbard is that it results from a cross-wiring or cross-activation of sensory neurons in various parts of the brain such that, for instance, brain regions involved in color perception get cross-activated with sensations of numbers. Some extraordinary mathematical ability results from synesthetic perception of number, as most clearly seen in the savant Daniel Tammet. Creativity and synesthesia share neural complexity in common.

Development of Scientific Talent

Research into talented and gifted high school students who compete in and win national and international science competitions makes clear that achievement in science starts with a unique combination of intelligence, drive, emotion, and personality of students as they navigate the world of world-class—and competitive—science. Indeed, a critical question examined by psychologists of science is a developmental question: Where does scientific creativity come from? Like all creative achievement, scientific talent has a life-span trajectory. Certain children, based on a combination of talent and training, are more likely to go into science than others, and even particular kinds of science than other kinds. But going from childhood interest to adult scientific achievement is a long and complex process. Many obstacles and life circumstance intervene and many potential scientists change career paths. Moreover, once a scientist, there is a wide range of creative ability and the focus in this chapter is on creative talent and achievement in science. What, then, are the psychological factors behind creative talent and achievement in science and how do these factors change across the lifespan? Taken as a whole, the literature on these questions does provide some pieces to the puzzle of scientific productivity.

Scientific Creativity and Talent Across the Lifespan

Historically, the first scientific work on the development of scientific talent and creativity develops was conducted by Francis Galton in the 1870s. Most relevant to the current chapter, Galton's book *English Men of Science* in 1874 pioneered work on birth-order and scientists and found that scientists were more likely to be first-born children than non-scientists.

The first systematic and longitudinal research program that shed light on the development of scientific talent was conducted by Lewis Terman, beginning in the 1920s. His study included children if they had tested IQs of 140 or higher. More than 1500 children qualified and participated, with the first sample being tested in 1921 (when most of the children were about 10 years old). They were assessed once or twice a decade for the next 60 years. By following the cohorts over their entire adult lives, Terman and his colleagues were able to answer the important question of what happens to our brightest children. Do they go on to very productive and creative careers? The answer is "yes" to productive, but "not really" to creative. Although the sample as a whole achieved higher than normal levels of education and career success, if one uses standard creativity criteria (impact, productivity, and honors and awards), the Terman group in general was surprisingly uncreative over the course of their careers. No major writers, artists, or scientists emerged from this 'genius' level IQ group. Indeed, two future scientists who were tested by Terman—William Shockley and Luis Alvarez—but did "not make the cut" went on to outperform any of the Terman subjects by receiving Nobel prizes in physics.

The next major longitudinal investigation that focused even more closely on scientific talent development was begun by Julian Stanley at Johns Hopkins in the 1970s and has continued under the leadership of Stanley's students Camilla Benbow and David Lubinski, now at Vanderbilt University. The project is known as the Study of Mathematically Precocious Youth (SMPY) and it targets children under the age of 13 who show precocious signs of mathematical talent. Results from these studies have reported that precocious ability does predict achievement in high school and in college. More recently, Benbow and colleagues reported that approximately 90% of the SMPY sample go on to earn bachelor's degrees, slightly less than 40% get master's degrees, and about 25% receive doctorates. These figures are well above the base-rates for such degrees in the general population (with 23%, 7%, and 1% being the national figures respectively). Similarly, Lubinski and colleagues reported in 2006 that talent-search SMYP participants who scored 700 or above on either one of the SAT subscales (quantitative or verbal) before age 13 went on to have very successful careers 20 years later, especially in math, science, or engineering. For example, nearly half of them were

post-secondary teachers, scientists, or engineers. More specifically, about 15% of the talent-search females and about 9% of the talent-search males were in tenure track or tenured positions by age 33—rates much higher than the general population.

Most directly relevant to scientific creativity and talent, Rena Subotnik and her colleagues were the first psychologists to systematically examine the longitudinal paths of scientifically talented young people. She focused on finalists and semi-finalists for the country's most prestigious and elite science talent search competition, the so-called Westinghouse competition (now known as the Intel competition). It involves more than 1500 high school juniors and seniors every year, of which the top 300 are semi-finalists and the top 40 are finalists. Subotnik followed up one cohort of semi-finalists from 1983 and were able to collect data on approximately 100 of the 300 finalists/seminfinalists. Eight years after being semi-finalists and finalists, 49 of the 60 males (82%) but only 25 of the 38 females (66%) were still in science or science related fields (including graduate school. Moreover, as Joseph Berger has reported on the entire sample of Westinghouse finalists, they do garner awards and recognition for their continued excellence for scholastic and career achievements. For instance, in the entire population of finalists up through 1994 five have gone on to earn Nobel prizes, 28 have become members of the National Academy of Sciences, and at least eight MacArthur Fellows have been awarded.

A few researchers have addressed the question of who is likely to make significant contributions to science and if so did they show early signs of their talent. Feist, for instance, examined the development of scientific interest in Westinghouse finalists and members of the NAS. For Westinghouse finalists, both men and women knew science was for them at an equally young age—by age 12. Members of the National Academy also developed an interest in science at a very early age, with 25% knowing they wanted to be a scientist by age 14%, 50% knowing by age 18%, and 75% knowing by age 20. In terms of first realizing they had talent for science, 25% of the NAS members realized their talent by age 13%, 50% by age 16%, and 75% by age 21. The range was ages 5 to 33. Finally, NAS members began doing science early, with 75% having participated in formal research by age 21, and no gender difference between men and women. Half of the NAS members had published a scientific article by age 23, and at least one member had published by age 16. Those who go on to have real talent in science as adults seem to realize at a young age that they want to become a scientist. Given that most college students change their major many times during their 4 years as an undergraduate, to have a group know by the end of high school or before that a particular career is right for them is quite remarkable. Early and clear insight into one's career calling is often an indicator that one knows where one's talents lies, and indeed such "crystallizing experiences," as Howard Gardner has called them, are frequently seen in adolescents who go on to be our most creative adults.

Age and Scientific Productivity

The oldest and most established question concerning the development of scientific productivity is of growth curves and publication rates, that is, how productivity (i.e., publication rates) changes with age. As Dean Simonton has often reported in his reviews of the literature, the findings have converged on the conclusion that the relationship between age and productivity in science (and other professions) is curvilinear: Scientific productivity increases steadily over the first 20 years of a scientist's career, plateaus, and then gradually declines. In other words, it forms an inverted-U.

Similarly, in a study of National Academy of Science (NAS) members Feist reported three unconditional growth curve models that were constructed to test Simonton's curvilinear model of age and productivity, namely a linear model, a quadratic model, and a cubic model. Each model provided a close fit to the data, suggesting that publication rates increase over time. Out of the three models, however, the curvilinear model provided a better fit than the linear model, and the cubic model a better fit than the curvilinear model. In other words, a model with two peaks (approximately 20 years into one's career and then again at the very end) was the best model of age and productivity.

Related to age and productivity there is the question of whether early recognition of talent and producing works early in life predicts later levels of productivity. The empirical consensus is that early levels of high productivity do regularly predict continued levels of high productivity across one's lifetime. Those who are prolific early in their careers tend to continue to be productive for the longest periods of time.

Lastly, there is also the question of whether the age at which one's talent for science is first expressed predicts lifetime achievement in science. Regarding age of recognized talent, Feist predicted that in a sample of NAS members, age of talent should predict age of publishing and obtaining the PhD, which in turn should predict productivity and impact. Results showed that the four precocity variables were modestly positively correlated with age of first publication, which is an intermediate variable between precocity and achievement. In other words, the younger NAS members were when they and others recognized their scientific talent, when they wanted to be a scientist, and when they first conducted scientific research, the younger they were when they published their first paper. Age of first publication in turn predicted total publication rate over the lifetime, meaning the earlier one publishes the more productive one will be. This pattern of relationships—from precocity to age of first publication to lifetime productivity—implies an indirect connection between precocity and publication rate. The only precocity variable that predicted lifetime productivity was age that one first conducted formal research.

Creative Personality in Science

The development of scientific talent, achievement and productivity over the life course is one focus of psychologists of science who are interested in scientific creativity. Another focus is the unique personality characteristics of highly creative scientists.

One model of personality that explains the connection between personality traits and behavior, including scientific creativity, is the so-called functional model of personality. The basic idea of this model is that traits function to lower behavioral thresholds. If a person has a particular trait, then corresponding behaviors are more likely (have lower thresholds) in given situations. A person with a friendly personality, for instance, is more likely to behave in a friendly and warm way than a person without such a trait.

Applied to creative behavior, certain personality traits make creative thought and behavior more likely. What then are these personality traits, in particular as they relate to scientific creativity? A meta-analysis published in 1998 by Feist addressed the question of which traits make creativity and eminence in science more likely and what their magnitude of effect was (see Karwowski and Lebeda for a recent qualitative review of the general creativity and personality literature). The traits can be arranged into three psychologically meaningful categories: cognitive, motivational, and social.

Cognitive Traits

A consistent finding in the personality and creativity in science literature has been that creative and eminent scientists tend to be more open to experience and more flexible in thought than less creative and eminent scientists. The few studies that reported either no effect or a negative effect of flexibility in scientific creativity used student participants. For instance, in 2003 Feist and Barron examined personality and creative achievement in a 44-year longitudinal study. More specifically, they found that personality variables (such as Tolerance and Psychological Mindedness) explained up to 20% of the variance over and above Potential and Intellect. Specifically, two measures of personality—California Psychological Inventory scales of Tolerance (To) and Psychological Mindedness (Py)—resulted in the 20% increase in variance explained (20%) over and above potential and intellect. The more tolerant and psychologically minded the student was, the more likely he was to make creative achievements over his lifetime. Scott Kaufman and colleagues recently reported that more than openness (cognitively engaging with fantasy, aesthetics, and emotions) more the intellect dimension of openness (i.e., cognitively engaging with semantic and abstract information) that is more closely associated with scientific creativity. (See Cognition)

Motivational Traits

The most eminent and creative scientists also tend to be more driven, ambitious, intrinsically motivated, and achievement oriented than their less eminent peers. Busse and Mansfield, for example, studied the personality characteristics of 196 biologists, 201 chemists, and 171 physicists, and commitment to work (i.e., “need to concentrate intensively over long periods of time on one’s work”) was the strongest predictor of productivity (i.e., publication quantity) even when holding age and professional age constant. Similarly, Helmreich and colleagues studied a group of 196 academic psychologists and found that different components of achievement and drive had different relationships with objective measures of attainment (i.e., publications and citations). With a self-report measure, they assessed three different aspects of achievement: “mastery” preferring challenging and difficult tasks; “work” enjoying working hard; and “competitiveness” liking interpersonal competition and bettering others. Helmreich and his colleagues found that mastery and work were positively related to both publication and citation totals, whereas competitiveness was positively related to publications but negatively related to citations. Being intrinsically motivated (mastery and work) appears to increase one’s productivity and positive evaluation by peers (citations), whereas wanting to be superior to peers leads to an increased productivity, and yet a lower positive evaluation by peers. The inference here is that being driven by the need for superiority may backfire in terms of having an impact on the field. (See Motivation)

Social Traits

In the highly competitive world of science, especially big science, where the most productive and influential continue to be rewarded with more and more of the resources, success is more likely for those who thrive in competitive environments, that is for the scientists who are self-confident, dominant, arrogant, and hostile. Bruno Lemaître, a geneticist who carried out three studies that won a Nobel Prize—only to see the prize go to head of the lab and not him—argues for the power of narcissism, need for power and visibility, in high level science. Similarly, Feist in the 1990s reported a structural equation model of scientific eminence in which the path between observer-rated hostility and scientific eminence was direct and the path between arrogant working style and eminence was indirect but significant.

The scientific elite also tend to be more aloof, autonomous of social influence, asocial, introverted and have more of an internal locus of control than their less creative peers. In a classic study from the 1950s concerning the creative person in science, Anne Roe found that creative scientists were more achievement oriented and less affiliative than less creative scientists. Recently, Kirsch and colleagues reported that need for autonomy was strongest personality predictor for creativity in the social sciences (psychology and education).

To summarize the distinguishing traits of creative scientists: they are generally more open and flexible, driven and ambitious, and although they tend to be relatively asocial and autonomous, when they do interact with others, they tend to be somewhat prone to arrogance, self-confidence, and hostility.

Creative Cognition in Science

As Ryan Tweney wrote: Science, by its very nature, is a cognitive act. We could add that creativity, by its nature, is a cognitive act. Hence, creativity in science inevitably must involve unique and consistent cognitive processes and strategies. It does and psychologists of science have concluded that at least four cognitive processes are consistently involved in scientific creativity, namely analogy, metaphor, visualization, and fluency and flexibility of association.

Analogy

Analogy involves seeing how something new (target) is like something old (source). Our mind seems to do this automatically and intuitively almost any time we are confronted with a new idea or new experience. Analogy is one of the more ubiquitous ways the brain takes sensory experience and gives it meaning. In *The Way We Think*, the cognitive scientists Gilles Fauconnier and Mark Turner put it this way: "Analogy has traditionally been viewed as a powerful engine of discovery, for the scientist, the mathematician, the artist, and the child."

There is a well-developed literature on the importance of analogy and metaphor in scientific problem solving and creativity. The consensual conclusion from this literature is that analogy is a crucial problem-solving heuristic that allows scientists to apply schemas, models, and mental maps from known to unknown domains in order to solve problems. The success and richness of the analogy depend on how deep the similarity is between old and new. Associations no doubt play a critical role in analogical thinking, with the similarity being touched off via an association. In science, these analogies also often serve as the foundation for hypotheses.

Let's look at one of the most powerful scientific analogies in the history of science: Darwin's tree branch analogy and evolution. Species that are more closely related are closer together on a common branch. This branching analogy is used in current taxonomic systems. The branching tree analogy also makes clear that evolution is not a linear progressive process with humans at the apex, as many evolutionists at the time had argued. Rather, evolution consists of many dead ends and extinct species and is simply a process of the birth, growth, and death of species, all going back to one common origin. This was a truly powerful and revolutionary insight: *all life* on the planet is related! Another foundational analogy used by Darwin was the comparison between natural selection and artificial selection seen in human breeding of plants and animals. Indeed, Darwin's first chapter to *Origins* begins with the well-known principles of "Variation under Domestication," which lays the foundation for using similar principles in nature in the next chapter, entitled "Variation under Nature."

Analysis of historical cases also consistently reports creative scientists often use analogies to solve problems. In *Psychology of Science: Contributions to a Metascience*, Dedre Gentner and Michael Jeziorski compared the way two physical scientists (Robert Boyle and Sadi Carnot) used analogies to the way alchemists employed them. They concluded that following particular rules when using analogies (for example, avoiding mixed analogies, understanding that analogy is not causation) was the key to distinguishing scientific from pseudoscientific reasoning. But Carnot and Boyle had different styles of analogical reasoning: the former relied on a single analogy, deriving principles from it, whereas the latter preferred to work with a whole family of analogies. Similarly, Nancy Nersessian observed that James Clerk Maxwell used analogies iteratively, that is, he constantly modified them to fit his growing understanding of the constraints of the target domain. Michael Gorman has demonstrated that Alexander Graham Bell deliberately "followed the analogy of nature" and used the human ear as a mental model for his telephone; like Maxwell, he was able to modify this analogy as he learned more about his target domain.

Metaphor

Metaphor is similar to analogy in that they both involve applying similarity from an old source to a new target. In this sense many metaphors are analogies. The essence of metaphor is an "as if" comparison, thinking about X as if it were Y. By applying one phrase or idea to another different one that is not literally the same, we again make the unknown known.

As psycholinguists as George Lakoff, Mark Johnson, and Steven Pinker have made clear, metaphors are so ubiquitous that we often do not even recognize the metaphorical nature of much of our thought. For instance, Pinker gives the following examples of the metaphorical use of *went*: "the messenger went from Paris to Istanbul," "the inheritance went to Fred," "the light went from green to red," and "the meeting went from 3:00 to 4:00." Only in the first phrase is *went* used literally to mean moving from one place to the other. In each of the other instances, *went* is used metaphorically. Our minds seem well equipped to make such connections and to transfer similarities as a way of understanding the new and unknown.

It is no surprise, therefore, that science is replete with metaphors. Indeed, most major scientific insights have involved some kind of analogical metaphor. Robin Dunbar has pointed out that metaphorical use of language is especially rampant in particle physics and evolutionary biology. Particle physicists refer to the different kinds of quarks as "top," "down," "bottom," "up," "charmed," and "strange." Such everyday common words could hardly be more literally removed from the abstract, unobserved, and probably unobservable quarks, and yet that is part of the joke or pun of the inventors of these terms. Mathematicians also commonly refer to equations as "beautiful," or "well behaved." Evolutionary biology is also littered with such metaphors: "the selfish gene," "kamikaze sperm hypothesis," or the "red-queen hypothesis" (from Alice in Wonderland), just to name a few. I would also point out that computer science is perhaps even more prone to metaphor: "user-friendly," "mouse," "crash," "boot-up," "file" "window," and so on. As Dunbar goes on to argue, however, there is good reason for such widespread use of metaphor in these fields: they are far removed from everyday experience and we simply have no words to describe the phenomena. Therefore, scientists have little choice but to either use metaphors or invent new technical terms. Sometimes scientists do the latter, but more often than not they choose the former, and the terms "strike us" as "warmer," and "friendlier" than technical jargon (note the metaphorical use of these words).

Metaphor and analogy are common in and out of science precisely because they are so useful to hypothesis and theory formation, thought experiments, creativity, and problem solving. They provide useful constraints to solutions to problems by focusing strategies and preventing random and fruitless searches for a solution. Scientists, and especially the best scientists, tend to use them more readily than novices and thereby go down fewer dead ends when trying to solve a problem. Of course, analogies and metaphors offer such cognitive advantage only if they are appropriate and useful. Often the more creative scientists have

a feel for (that is, an intuition for) a good and productive analogy or metaphor. When they are useful, they make problem solving much more efficient than it would be otherwise.

Visualization

Another cognitive strategy or heuristic often used in but not unique to scientific creativity is visual imagery. The historian of science Arthur I. Miller in his book *Insight of Genius* and elsewhere has written at great length about the important role of visualization and imagery in science. After detailing case after case in the history of physics, he summarized his main point about the role of visual imagery in creative scientific thinking: visual imagery plays an important role in scientific creativity (for example, Einstein's thought experiments) and in scientific advance, and it can carry truth value (for example, Feynman diagrams).

Einstein is one of the more noteworthy examples of the importance of visual thinking. The gestalt psychologist Max Wertheimer spent hours and hours interviewing Einstein in 1916 about how his theory of relativity came about, and among other things, Einstein remarked that he rarely thought in words and used words only after the idea came to him so that it could be communicated to others. The physical world after all is made up of objects and the ability to think in images would be of great help in solving physical problems. Visual intuition, to be sure, was crucial for all of Einstein's great insights: imagining himself traveling at the speed of light, imagining himself simultaneously jumping off of a roof and dropping a stone (which led to his insight that gravity and acceleration are relative quantities), and imagining two observers riding on either the northern or southern pole of a magnet. Most of these visual thought experiments occurred in the twenty-year period between 1895 and 1915, and by all accounts this was the period of Einstein's singular creative genius. In fact, other physicists such as Richard Feynman remarked on the lack of creativity in Einstein's later life being connected to his decline in his use of visual imagery.

Physics as a whole became less comprehensible when it moved beyond what we observe in everyday life and can easily visualize. Quantum mechanics is the prime example because it deals with matter at a fundamentally different level than the observable Newtonian world. From about 1925 (with the death of Bohr's "atom as solar system" model) until 1949, quantum physics moved decidedly away from the use of visual images and toward purely mathematical formulations. In Niels Bohr's 1922 Nobel prize lecture, the limitations of his own model were already clear to him: "We are therefore obliged to be modest in our demands and content ourselves with concepts which are formal in the sense that they do not provide a visual picture of the sort one is accustomed to require." In 1949, however, Richard Feynman was to change this by advancing his graphic "Feynman diagrams" to explain how subatomic particles interact. As quoted in Gleick's biography *Genius*, Feynman described what he was doing with Feynman diagrams: "What I am really trying to do is bring birth to clarity, which is really a half-assedly thought-out pictorial semi-vision thing. I would see the jiggle-jiggle-jiggle or the wiggle of the path. Even now when I talk about the influence functional, I see the coupling and I take this turn—like as if there was a big bag of stuff—and try to collect it away and to push it. It's all visual. It's hard to explain." Most recently, string theory has added concreteness to a concept that right now is orders of magnitude away from being observed, namely, "strings." Strings are an excellent example of both how visual images and metaphor are used in the construction of scientific theory.

Fluency and Flexibility of Associations

In addition to the cognitive processes already discussed (analogy, metaphor, and visualization), a number of cognitive traits cluster around creative ability: remote and loose associations, over-inclusive and disinhibited thinking (latent inhibition), fluency, flexibility, novelty and originality. Sarnoff Mednick's theory of remote associations underscores the associational richness of creative thinkers. J. P. Guilford built a theory of creativity around ideational fluency, flexibility, and originality, arguing that creative thinking results from having many ideas (fluency) that cross boundaries and categories (flexibility) and that are novel and original. Hans Eysenck proposed that the defining cognitive characteristic of highly creative individuals, besides at least a moderately high level of intelligence, is their over-inclusive and disinhibited thinking. In other words, creative people automatically have a wider range of associations and have difficulty inhibiting associations and focusing on a narrow range of relevant stimuli. For this reason, they score high in what Eysenck called "psychoticism." Finally, Dean Simonton, borrowing from Donald Campbell, put forth the chance configuration theory of creativity, which posits that ideational and associational fluency are the foundation for creative thought. In a very Darwinian fashion, ideas are first generated in great number (variation), get combined (chance permutation), and those permutations that are adaptive and useful get selected and reproduced (retention). Just as in biological natural selection, some ideas are adaptive solutions ("hits") and these get selected and retained, whereas others are not adaptive or useful ("misses") and these do not survive. Creative scientists, like all creative people, are able to produce a richer and deeper set of associations, many of which are not useful, but some of which are. These survive and become the foundation for creative ideas in science.

Conclusion

Science would not exist if it were not for the creative ideas of its participants. The psychology of science has empirically addressed and answered the questions of who becomes interested in and has talent for creative science. The answers provide particular profiles of neural complexity, development, personality, and cognition. This chapter summarizes these literatures and provides an integrated profile of the creative scientist. For example, the creative scientist compared to the less creative scientist is called to the life of science at a younger age, remains highly productive, is more confident, asocial, flexible, and hostile, and solves problems more often using analogy, metaphor, and visual imagery.

Glossary

Authenticity Behavior that is a true reflection of one's self. An indicator or outcome of self-actualization. It is also a criterion of creativity in many Eastern views where authenticity is more important for creativity than originality.

Divergent thinking The capacity to generate ideas, many of which are original. Tests of divergent thinking are used in correlational studies of self-actualization and creativity, though divergent thinking only represents a potential to be creative. It is not a guarantee.

Intrapersonal intelligence A specific domain of talent, increasingly recognized in creative studies, which in many ways parallels self-actualization.

Self-actualization Openness to and acceptance of one's true self. Leads directly to openness to experience, spontaneity, and creativity. Self-actualization is the epitome of psychological health.

Theories of Self-actualization

Self-actualized individuals are thought to be creative. Abraham Maslow, for example, felt that self-actualization and creativity are interdependent. He described how creativity facilitates self-actualization and self-actualization facilitates creativity. In Maslow 1971 even concluded that creativity and self-actualization “may turn out to be the same thing” (p. 57).

Carl Rogers, another leading humanistic psychologist, argued that:

the mainspring of creativity appears to be the same tendency which we discover so clearly as the creative force in psychotherapy – [a person's] tendency to actualize ... to become one's potentialities... the individual creates primarily because it is satisfying... because this behavior is felt to be self-actualizing. (1961, pp. 351–352)

Empirical Research on Creativity and Self-Actualization

Rogers and Maslow developed their theories of self-actualization by drawing from their experience conducting psychotherapy. Such work gave them extensive information about individuals; however, generalizations from clinical observations are often questioned. This is because (a) generally a small number of persons are observed, and (b) those persons may be atypical in many ways – after all, they are receiving psychotherapy. Fortunately, more rigorous research followed the propositions of Rogers and Maslow and also examined the relationship between self-actualization and creativity.

Some of this research failed to support the relationship between creativity and self-actualization. For instance, nonsignificant (and low) correlations were between four measures of creativity and self-actualization, the former operationalized with the Remote Associates Test (RAT), and the latter with the Personal Orientation Inventory (POI). These results are not entirely convincing, however, in part due to the measure of creativity used. The RAT may be verbally biased, for example, and in this research its reliability was in the range between 0.51 and 0.67, which is marginal at best. Convergent validity coefficients were similarly marginal

[☆] *Change History:* August 2019: Mark Runco extended the glossary. New research was added, including a discussion of how recent discussions of definitions of creativity should include authenticity, as well as originality and effectiveness, in order to capture Eastern views. The update also clarified the testing issues involved in studies of self-actualization and tweaked the view of the creative process.

This article is an update of M.A. Runco, Self-Actualization, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 335–336.

($0.01 < r_s < 0.48$), which can be indicative of dubious construct validity. The point is that the lack of a relationship between creativity and self-actualization may reflect the measures employed.

Some researchers have operationalized creativity with the Torrance Tests of Creative Thinking (TTCT), which are quite widely recognized as a reliable estimate of the potential for creative problem solving. They are unlike the RAT in that they examine the capacity for divergent thinking and the production of idea. Note the emphasis on potential; no test of creativity guarantees actual creative performance. Tests are samples and at best accurately predict future behavior. Note also the emphasis on problem solving. Some creativity may be more self-expression than problem solving – and this may be especially true of the creativity that is related to self-actualization. Yet another measure of creativity used in this line of research was the Similes Preference test.

Murphy et al. (1976) found that Personal Orientation Inventory scores were significantly and positively correlated with the elaboration index from the TTCT. They did not provide the actual correlation coefficient, so it is impossible to really interpret the relationship. POI scores were unrelated to the originality fluency TTCT scores, and were unrelated to performances on the Similes test. The result with originality is disconcerting because it is usually taken to be the key ingredient of creativity.

Runco and his colleagues noted that the relationship between creativity and self-actualization could only be accurately assessed if creativity was operationalized in terms of personality and process. These reflects two common perspectives on creativity. The personality approach posits that there are core characteristics or traits that are functionally associated with creative behavior [see Personality]. The process orientation posits that creativity may not result in tangible products but should be understood as something that is protracted and occurs over time.

Maslow was explicit about the distinction between personality and product:

SA [self-actualized] creativeness stresses first the personality rather than its achievements, considering these achievements to be epiphenomena emitted by the personality and therefore secondary to it. It stresses characterological qualities like boldness, courage, freedom, spontaneity, perspicuity, integrity, self-acceptance, all of which make possible the kind of generalized SA creativeness, which expresses itself in the creative life, or the creative attitude, or the creative person. I have also stressed the expressive or Being quality of SA creativeness rather than its problem-solving or product making quality (1968, p. 145).

Maslow later gave these traits when defining self-actualization: acceptance of self, others, and nature; detachment; a desire for privacy; autonomy; resistance to enculturation; problem-centering; and democratic character structure. Most of these are also characteristic of the creative personality.

Runco and his colleagues used two well-respected measures of the creative personality: the How Do You Think Test (HDYT) and the Adjective Check List, which has a Creative Personality scale. They also administered the Self-Actualization Scale (SAS). Four scores were derived from the HDYT responses, and each was significantly and positively correlated with the SAS scores. It thus appears that the relationship between creativity and self-actualization does indeed depend on the measures employed. In particular, the results underscored the need to measure creativity with personality traits, at least when the interest is self-actualization. Importantly, although the findings were contrary to the other two empirical studies on this topic, they were consistent with the observations of Rogers and Maslow. This suggests that the findings are trustworthy because they were predicted first by theory and then confirmed with empirical tests.

Lynne Buckmaster and Gary Davis (1985) also reported a positive and significant correlation ($r = 0.73$) between self-actualization and a measure of creative personality traits. In particular, Buckmaster and Davis uncovered a creativity factor that accounted for a significant portion of variance in an eight-factor factor analysis. This analysis included the Reflections of Self and Environment (ROSE) measure, which is a self-report focusing on self-actualization. There are two questions with this factor analysis: First, the creativity factor accounted for only 18.9% of the variance in the scores, perhaps because it was a fairly select sample of subjects. The participants were all students in a creativity course. This may have restricted the range of scores. It was also a relatively young sample of participants, which is an issue because self-actualization might require some experience and maturity. There is a debate in the psychological literature about the possibility of self-actualization in young persons. The second question concerned the ROSE index, which was more correlated with the creativity scores than it was with the POI scores ($r = 0.26$).

The low correlation with the POI again raises the issue of construct validity. Still, by and large these results were consistent with those of Runco and his colleagues which were summarized above. Thus in the two studies that relied on personality measures a positive and significant correlation was found between creativity and self-actualization.

The Adjective Check List was mentioned above and used in some of the personality research. It is a self-report containing 300 adjectives. Respondents indicate which adjectives are self-descriptive. The vast majority of persons whose self-actualization scores were in the top 25% of the sample used these adjectives to describe themselves: Adventurous, Alert, Appreciative, Clever, Dependable, Friendly, Helpful, Honest, Loyal, Active, Adaptable, Capable, Easy-Going, Formal, Humorous, Intelligent, Interests Wide, Kind, and Mature. None of them described themselves as Commonplace, Conceited, Cruel, Despondent, Distrustful, Dull, Gloomy, Queer, Slipshod, Stolid, Sulky, Unintelligent, Unkind, or Unstable. These are interesting but socially desirable responding was possible.

Creativity, Health, and Possible Underlying Causes

Both creativity and self-actualization are indicative of psychological health. As is the case with most signs of health, however, it is not easy to determine which comes first. It is possible that self-actualization allows the individual to be creative, or that the creative

tendency supports self-actualization. It is also possible that both are results of a third variable. This third variable might be the capacity for effective coping, adaptability, or intrapersonal intelligence. Recall here what Rogers said, and was quoted earlier, that self-actualization and creativity both reflect an underlying motivational force. Intrapersonal intelligence is included in this discussion because it is one of the distinct domains from Howard Gardner's well-known framework. The other domains are inter-personal, verbal, mathematical, spatial, bodily-kinesthetic, musical, and naturalistic. Gardner goes into some detail about the unique processes underlying each of these domains, including the intrapersonal domain.

Authenticity is a good candidate for a third variable that leads to both creativity and self-actualization. Authenticity is associated with a low level or lack of self-censorship, as well as a resistance to conformity. As a result the individual expresses his or her true self. The resistance to conformity and lack of self-censorship can both facilitate creative behavior. Self-actualization is impossible without authenticity. The individual is a unique individual, with good and bad tendencies, and the only way to self-actualization is through the acceptance of both. A lack of self-censorship is again useful, if not vital.

One interesting thing about authenticity is that in the past decade various researchers have argued that it is more important for creativity than is originality, at least in Eastern Cultures (Khurkhurin, 2014; Tan, 2016). Including authenticity in a definition of creativity therefore gives is more cross-cultural validity, and this definition would be entirely aligned with the humanistic view of creativity, which also includes authenticity.

It does appear that some creative persons are not self-actualized. Some are certainly not healthy. In fact, creativity can be downright destructive [see Destructive Creativity] and, as Robert McLaren (1993) argued, there may be a dark side to creativity [see Dark Side of Creativity]. This may be manifested in creative but destructive discoveries and inventions, such as thermonuclear weapons, and in the not uncommon self-destructive behaviors of some creative persons. This self-destruction may take the form of suicide or alcoholism.

Conclusions

There is evidence that creativity and self-actualization are related. This relationship was predicted by the theories of Carl Rogers and Abraham Maslow and was apparent in both clinical observations and, later, at least two correlational studies. As is the case with all correlations studies, however, there is some uncertainty about the direction of effect: creativity may lead to self-actualization, or self-actualization may support creativity. They may both reflect a third variable, such as coping or adaptability. And neither guarantees the other.

There are many cases of unhealthy creative persons. This is not much of a surprise because there are many different ways to be creative. Rhodes went into some detail about this when she distinguished "deficiency creativity" from "being creativity." People are creative for varied reasons. In addition, some individuals are creative in their work, and some in their leisure (See Everyday Creativity). Some are creative when they solve problems; others are creative only when they are not threatened by problems. Although some creative persons may be self-actualized, and that self-actualization may in fact be necessary for their creativity, other individuals may be creative without self-actualizing. Both creativity and self-actualization are multifaceted constructs, and this gives them any number of possible intersections.

Introduction

The word “serendipity” commonly refers to making a discovery by chance and sagacity when one was looking for something else and—by extension—the capacity and the art of making a discovery in unexpected circumstances. This accidental meeting offers an opportunity for the reorientation and development of new objectives, exploration of unexpected results, and transformation or creation of new theories or practices.

There are numerous examples of serendipitous discoveries in many disciplinary fields: penicillin, laser, aspirin, X-rays, radioactivity, Viagra, Post-It, nylon, Kevlar, the stethoscope, jeans, Coca-Cola, abstract painting, the hot air balloon, and the Tatin tart. This list of serendipity cases shows the richness and extent of a phenomenon that has common relevant traits beyond the diversity of cases and contexts. Far from being a simple buzzword or marginal and peripheral phenomenon, serendipity is an essential mechanism in the creative processes of research, discovery, theoretical construction, and practical action. Starting from the origin of the concept of serendipity, this article proposes a definition of the phenomenon as a creative process. The characteristics of the serendipitous process, the resulting products, the people who shape them, and the role of the context are then presented. The transdisciplinary dimension of serendipity is then highlighted. This transdisciplinarity finally links up with the indiscipline inherent to serendipity.

Origin

The word “serendipity” has its source in the literary field. It was coined by the British writer Horace Walpole (1717–97), in a letter written on January 28, 1754, to his friend Horace Mann. Serendipity refers to unexpected discoveries, made by accident. Walpole was explicitly inspired by the title of a tale of Persian origin by Amir Khusrau (1253–1325) that he had read as a child in the version by Louis de Mailly entitled *Travels and Adventures of the Three Princes of Serendip* (1722). During their adventures, the heroes multiply unexpected discoveries of things that they described them on the basis of clues without ever having seen them (Van Andel and Bourcier, 2009). Walpole invented the word “Serendipity” from the old Sri Lankan name “Serendip,” from Persian *Sarandip* and Arabic *Sarandib*. It was relatively dormant until it was introduced in sociology of science by Merton in 1945 in his article *Sociological Theory* (Merton, 1945). This conceptual awakening reactivated the notion by making it an important element of the research process underlying accidental discoveries, chance, or wisdom of valid results that were initially not wanted.

Merton clarified his thought in a new article in 1948 (Merton, 1948) and in a work cowritten with Barber in 2004, *The Travels and Adventures of Serendipity* (Merton & Barber, 2004). A “serendipity pattern” designates a mechanism in which the observation of unanticipated, abnormal, and strategic data becomes an opportunity to develop a new theory or expand an existing theory. The idea of unanticipated data or unexpected results opens the possibility of observing or even producing accidental and unforeseen results at the start of the research process.

Serendipity can be defined as a complex and varied phenomenon including the process of its genesis (between chance and its shrewd exploitation), the final product resulting from this process (cases and facts of serendipity), as well the ability or the art of making an unexpected discovery. A process, a product, and an ability are three key ingredients that help identify serendipitous production.

Process and Product

As a creative process, serendipity is characterized by a double movement: first an unexpected discovery that emerges by chance in the course of research or a planned action, then in a second phase the understanding and use/exploitation of this unforeseen element to draw a new idea, hypothesis, theory, or practice likely to reconfigure more or less radically the work in progress. Serendipity is not simply chance, nor an isolated stroke of genius or a “eureka” suddenly imposing a solution; it implies in a complementary way the wise, original, and relevant exploitation of an unexpected discovery. Diverting attention/focusing on the seemingly determined search for something, chance is not perceived as a negative and irrational effect to neglect or eliminate from the current process, but on the contrary positively as a heuristic opportunity to explore and exploit creatively new avenues for research. Serendipity enacts the double mechanism at work in a creative process (Guilford, 1956): the divergence phase (in this case triggered by an unforeseen and happy accident) that allows the exploration of new ideas and possibilities, and the convergence phase that aims at the original, intelligent, synthetic, and adapted exploitation of these new lines of thought. Accidental divergence–exploration offers the opportunity to take a step aside from the deterministic linearity of a conventional research approach, and convergence–exploitation allows the production of new ideas, hypotheses, or products.

Among the famous examples of discoveries and inventions made by chance and identified as cases of serendipity is the invention of Velcro by the engineer Georges de Mestral (1907–90). This case illustrates well the double movement of the serendipitous process. Georges de Mestral accidentally discovers something he was not looking for and derives a new idea and product from it. While walking his dog, he noticed that the burdock fruits cling to the hair of his dog and to his own socks. Not content to simply get rid of these burdock fruits to continue his journey, he begins an exploratory quest to examine them under the microscope and discovers that they are equipped with micro-hooks. This phase of study and exploration is followed by a more convergent phase of exploitation of this discovery with the idea of using this process of hooks that cling to a fabric, a nylon textile closure. The transition between the accidental discovery (in 1941) and the invention and innovation of the final product took 10 years to materialize in a patent (in 1955), following many experiments and attempts.

Velcro (a portmanteau word formed out of the words *velvet* and *hook*; in French “velours” and “crochet”: “qui s’accroche au velours”/which clings to velvet) is a typical case of bionics in the sense that it is inspired by the observation of a plant (in this case a micro-hook system) to draw, after questioning and analysis, a technical application by biomimicry. The double process of serendipity (chance encounter and exploitation of its potential) leads to products of invention and innovation subject to variation according to the case-types and the contexts. The example of Velcro is thus considered a typical case of “true serendipity” (Roberts, 1989) in the sense that the researcher made an accidental discovery of something that he did not specifically seek and which was not part of his current scientific concerns.

The inventions of microwaves, Lysergic acid diethylamide (LSD), or laminated glass are other examples of products resulting from ideas found by chance or by accident. These strong forms of serendipity in unexpected discoveries of ideas or things that were not sought are more nuanced in so-called pseudoserendipity cases according to Roberts (1989). These are certainly accidental discoveries, but which make it possible to achieve a desired goal by means other than those envisaged at the beginning of the research process. The researcher ultimately finds what he was looking for, but with an unexpected idea or means. After long efforts, the accidental discovery of the vulcanization process by Goodyear is a good example of pseudoserendipity. Other examples are Francis Pettit Smith’s boat propeller and Canon’s inkjet printing.

Beyond the true, pseudo-, or false serendipity, this complex process is each time a question of the degree and variation in bringing into play of chance, accident, the unforeseen, awkwardness, negligence, or error, with more or less anticipated issues, ranging from unknown unknowns (things we do not know we do not know) or unknown knowns (things we do not know we know) to known unknowns (things we know we do not know). In the case of the known knowns (things we know we know), one leaves without doubt the specter of serendipity since the researcher finds what he sought without chance intervening.

This almost tautological situation in which a researcher finds what he is looking for or what already existed by the application of a preestablished method is similar—by pushing his logic to the extreme—to a case of *Zemblanity*. The concept of zemblanity was invented by William Boyd (1952–Present) in his novel *Armadillo* (1998) in reference to the island of New Zembla situated at the antipodes of the island of Serendip, now Sri Lanka. Contrary to the spirit of invention and creativity inherent in Serendipity, Zemblanity refers to the faculty of systematically and deliberately making unhappy, unlucky, and expected discoveries and bringing nothing new.

Ability: The Serendipitist

People who produced serendipity cases or who make themselves available for such unexpected events—i.e., “serendipitists” according to Van Andel and Bourcier (2009)—are often perceived as having certain more or less specific abilities. They are described as curious observers, sometimes distracted, intuitive, judicious, and flexible, of independent spirit and preferring the unpredictable and freedom to the marked and authoritarian ways of knowledge production. These cognitive abilities to control make it possible to draw a secondary benefit from chance or accidents then transformed into happy phenomena that produce invention, innovation, and novelty.

A serendipitist has similar characteristics to a creative person. According to a multivariate approach to creativity (Sternberg and Lubart, 1995), the serendipitist mobilizes, on the one hand, cognitive factors with his strategic intelligence and his prior knowledge

that allow him to make a correct interpretation of an unforeseen fact and, on the other hand, conative factors related to his personality traits, motivations, and emotions. In terms of cognitive capacity, when a case of serendipity occurs, the researcher expresses his or her creative potential by identifying an unexpected fact or element and being able to redefine/reorient the process and task being resolved. Through a selective encoding process, he can locate in the environment or knows more or less the immediate information or phenomena in an apparently distant/disjoint relationship with respect to his questioning or problem to solve.

The personality, recognized serendipitists share the conative characteristics of more creative people (Feist, 1998). As perceived through the examples and analysis given above, the person or persons engaged in a process of serendipity, beyond their confidence in their own skills and their perseverance in their reflection and the search for innovative solutions, are more open to new experiences and risk-taking than conformists who are satisfied with the pursuit of certain and preestablished protocols. They are also more tolerant of ambiguity by accepting, wishing, or even challenging situations, assumptions, ideas, or approaches that are ambiguous and uncertain by appropriately responding and being able to exploit the unexpected effect generated by ambiguity, complexity, and uncertainty. Beyond the intra- and interindividual variations, the openness, and the ability to think outside preconceived boxes, serendipity requires the commitment of individuals capable at a specific moment of disengaging themselves from the mainstream and conformist thought, showing individualism and distance to really be able to confront and exploit the unexpected.

This was the capacity shown by Alexander Fleming in 1928, by serendipity, when he discovered the antibiotic properties of *Penicillium notatum*. While many bacteriologists had previously been confronted with the phenomenon of mold, but had simply shed their cultures, Fleming was able to identify this unexpected collateral fact of mold in the Petri dishes in which it was growing staphylococcal cultures and learned from them to develop penicillin. This cognitive flexibility was also expressed through his ability to observe differences and similarities by analogy, association, metaphor, comparison, or selective combination. The process of selective combination is here particularly illustrative, insofar as it makes it possible to precisely link elements to create a new idea, orientation, or product. A creative process of "bisociation" (Koestler, 1964) is at work in this unexpected rapprochement between distant elements or thought patterns that intersect to bring out new ones. The solution developed by Gutenberg for printing mobile characters on paper comes to him around 1450 during a day of harvesting (a domain of knowledge and practices which are very distant and apparently unrelated), when he observed at the right moment and in the right place the mechanism of a wine press that gives him the idea of the printing press.

Contextual Environment

It is necessary to avoid a romantic mystification of the isolated creative genius and the illusion of the figure of the serendipitist who was capable of spontaneously generating a stroke of genius fallen from the sky, like the famous apple falling on Newton's head. Discoveries by serendipity are not the products of a simple and sudden "eureka," spontaneously out of nothing, as an ex nihilo creation. They are not reduced to individual capacities alone, nor to a pure gift of heaven, but also take shape and meaning in a context more or less favorable to the emergence of serendipity. In the vein of the multivariate approach of creativity, the cognitive and conative factors are certainly at work in any creative process, including that of serendipity, but the contextual dimension also represents a complementary and equally decisive factor. As presented above, serendipity is certainly the combined result of a Process (P), the capacities of a Person (P) more or less involved in a collective and a specific Product (P), it is also at the same time subjected to environmental conditions, an external Press (P) according to the fourth P of the 4Ps' Model of Creativity (Rhodes, 1961).

The contextual variable (Press) covers the material conditions and the institutional, organizational, social, cultural, and cognitive structure in which the person operates the serendipitous discovery. Context then represents a micro- or macroenvironment that is more or less encouraging, permissive, and rewarding for the expression of dispositions favorable to serendipitous discovery. If "chance favors only the prepared minds" as Pasteur said, prepared minds can be more or less motivated and supported in the risk-taking inherent in the process of serendipity.

A research institution, laboratory, or organization should also be prepared for possible serendipitous discovery and if the case is to recognize it as such, accept and value it (Cunha et al., 2010). No institution can decree, plan, or control the random trigger of a serendipity process led by a sagacious researcher or group of researchers, but each institution can set up an eco-system that is culturally favorable to the emergence of serendipity. Organizational flexibility, a delineation of overly hierarchical structures, an openness to change and support for more peripheral and marginal visions and practices, as well as an epistemic vigilance in relation to unexpected discoveries are all provisions likely to favor serendipity, to collect it and welcome it.

This attention and time given to research outside the marked paths is reflected, for example, in a part of the working time left available for free research and development in the institution. In company research and development laboratories such as Shell, DuPont, 3M or Google, free personal research is between 10% and 30% of working time. The time and space available for this so-called clandestine or drawer research is not a guarantee of the success of a serendipitous discovery, but it is at least a signal in its favor, an attempt to institutionalize a process which is inherently unpredictable.

Transdisciplinarity: An Invitation to Indiscipline?

Discoveries, inventions, and innovations made through serendipity range from physics, chemistry, medicine, pharmacy, astronomy to geography, archeology, law, literature, music, painting, industrial production, sports, food products, or everyday life. Without

making a tedious inventory here, it is simply mind-boggling. Research indicates the concept is used in many disciplines in both the hard sciences and the humanities and social sciences. It is found among others in physics, chemistry, cognitive science but also in history, sociology, philosophy, epistemology, psychology, or in economics and management.

Serendipity is also reflected in new technologies of information and communication. The invention of the hypertext network of the World Wide Web is itself considered a case of serendipity (Van Andel and Bourcier, 2009). It seems obvious that the apparently free and hazardous circulation by navigation in an immense hypertext network of information evokes the basic principle of serendipity. Keyword searches on a search engine can certainly lead to the information or document sought, but they can also come up with unexpected results likely to arouse the curiosity and interest of the user. This 2.0 serendipity (Paveau, 2011) is exercised in the derivation through nodes links on the web and in relational social networks. These exploratory practices open to unexpected informational or relational discoveries on Google or Facebook which are programmed by powerful search algorithms. Under the guise of so-called unexpected discoveries, it is often mainstream elements that stand out, far from the authentic random emergence characteristic of serendipity.

The transdisciplinary ramifications of the concept of serendipity have thus been connected to the new technological possibilities of the Web. Through disciplinary fields, serendipitist researchers and practitioners behave—beyond their similarities and differences—as detectives (Eco, 1992) who, when faced with surprising and seemingly unrelated facts, try to confer an innovative intelligence by assembling them into a new coherent sequence.

Serendipitists of all disciplines use the reasoning by abduction. In addition to deduction and induction, abduction calls for more intuitive and exploratory reasoning, which provides the best possible explanation of a surprising and unexpected fact (Peirce, 1965). Induction and deduction are more conventional types of reasoning based on linear causality between a starting point and a point of arrival: from empirical observations to theoretical generalizations for induction and, conversely, for deduction from theoretical hypotheses toward their demonstration by empirical verification. In serendipity cases, the logical connection between facts and assumptions is more distant, unpredictable, and unexpected. An anomaly, accident, clumsiness, or any other unforeseen event engages an abductive reasoning on new possibilities and not strictly on what must necessarily be. The abduction (or retroduction) allows the creative and heuristic elaboration of new ideas, inventions, and innovations by managing to link facts or unlikely clues to plausible hypotheses.

Serendipitists, open to the unexpected and complex, implement not only nonlinear and nonprogrammed types of reasoning, but they seem to share a taste for interdisciplinarity (Darbellay et al., 2014) and indeed indiscipline (Catellin and Laurent Loty, 2013). The process of serendipity frees itself from the dictate of a preestablished method or protocol; it claims indiscipline in the freedom to think, to seek, and to find. Disruption or even the setting in crisis of disciplinary and conformist thought makes the detection of the unexpected possible (Darbellay, 2015). This act of epistemic disobedience that makes invention and innovation possible poses a new relationship with error or failure. These are no longer perceived/conceived as anxiogenic impasses or obstacles to be avoided at all costs, but on the contrary as opportunities to make new and happy discoveries. By giving a place to improvisation, serendipity offers the opportunity to dive “In the depths of the Unknown to find new!”, echoing the verse that concludes *Le voyage* (1859), the poem by Charles Baudelaire (1821–67).

Conclusion

The concept of serendipity which has its roots in literary history, history, sociology, and philosophy of science has been glamorized in the media. This success around a concept with a fascinating sound evokes a certain paradox. This paradox is the result of a tension between the recognized benefits of serendipity in major scientific discoveries and the functioning of research structures still highly disciplined and giving a massive weight to the organization and planning of research activities in which chance has very little space. Beyond the historical and prototypical serendipity cases described in scientific literature, the current and future possibility of new major serendipity cases probably implies an awareness in research institutions of the limits of the disciplinary model, and the place that can and must still be made to allow creative freedom for unexpected discoveries made through happy chance.

Glossary

Dispositional Factors These are internal causal influences, such as how personality or cognitive process affect a person's creativity.

Distributed Creativity An approach to research that focuses not on what is inside individuals but what happens between them.

Idealism A philosophical position that holds the primacy of thought and mind over the material world.

Innovation The process whereby an idea is developed, articulated, and implemented in a particular field, or through the creation and bringing to market of a product.

Integrative Transdisciplinarity A self-reflective, inquiry-based form of research that draws on systems and complexity theories to integrate pertinent information that found in multiple disciplines.

Materialism A philosophical position that holds the primacy of material factors over thoughts and ideas.

Methodological Holism An approach to research that takes the whole rather than the part (often the social system rather than the individual) as the unit of analysis.

Methodological Individualism An approach to research that takes the individual as the unit of analysis.

Situational Factors These are external causal influences, such as how an organization affects a person's creativity).

Social Creativity Definition Social creativity is an umbrella term for a number of different approaches to creativity that address social factors and issues in the study of creativity. There are considerable differences in the basic philosophical and methodological assumptions of these different approaches. The movement has drawn attention to relational creativity, creativity in relationships and groups, questioned and articulated the roots and philosophical stances of various approaches to creativity. Some researchers have attempted to articulate perspectives that do not view self and society as separate and mutually exclusive.

Unit of Analysis Refers to the most basic entity that is being studied, the who or what of as research project.

Introduction

Social creativity is an umbrella term used to describe a number of different approaches that go beyond psychology's traditional focus on the individual. It initially emerged in an effort to address social factors and issues in the study of creativity. The increased interest in social creativity has drawn attention to such topics as relational creativity, creativity in relationships and groups, the role of the environment in fostering or inhibiting creativity and has also questioned and articulated the roots and philosophical stances of various approaches to creativity. The psychology of women, discussed below, offers a useful entry point into the relevance of social creativity, since it is not possible to fully understand the creativity of women without an awareness of the historical social and psychological obstacles they have faced in participating in activities which receive high recognition, such as the arts and the sciences.

The study of social creativity has also opened up a considerable philosophical discussion, not least because the study of social creativity is not limited to the discipline of psychology, where traditionally most creativity research has been conducted. As a result, there are considerable differences in the basic philosophical and methodological assumptions of these different approaches. This in turn has led to a reflection on how understanding of creativity and creativity research themselves are created. Social creativity researchers have not shied away from tackling issues with a long philosophical history, and an important contribution of social creativity has been to lead researchers in multiple disciplines to reflect on how researchers have created creativity, what the underlying assumptions of every approach are, and how they in turn reflect the researcher's values, positionality, and cultural context.

Overview

The 1980s saw an expansion in the discourse of creativity to include a more “social” dimension. Until that time, creativity research had almost entirely been the province of psychologists and focused on individual persons and dispositional factors, such as personality. Starting with Simonton’s historiometric research in the mid 1970s and then into the 1980’s with Amabile’s social psychological approach, Csikszentmihalyi’s systems theory, and Harrington’s ecology of creativity, researchers began to include the world beyond the individual, exploring situational factors such as the culture of organizations and the role of gatekeepers in the arts and sciences.

The 1990s saw the publication of an increasing number of works addressing the implications of the social turn in creativity research. In 1995 Kasof applied attribution theory to creativity. The fundamental attribution error in social psychology involves making the characteristics of an individual, or dispositional factors, central in interpreting behavior and events. This happens at the expense of situational factors, or what is happening in the world rather than inside the individual. Attribution theory seeks to understand why people behave in a particular fashion. In the case of creativity, it stressed the role of situational factors and in particular social judgment. Kasof wrote his article at a time when Csikszentmihalyi’s systems model, which emphasized the role of “gatekeepers” in assessing who is and who is not creative, was gaining in popularity. As a result, social creativity began to be viewed as a movement predominantly concerned with the role of social judgment. This in turn created considerable controversy, not least because psychologists were concerned there would be a shift in the emphasis of creativity research to situational and sociological factors that psychologists considered inessential.

Also in 1995, Montuori and Purser critiqued what they saw as the dominant “lone genius” view of creativity in popular culture as well as its traces in academia, and made an argument for a more contextual and relational view of creativity (Montuori and Purser, 1995). Drawing on systems theory they emphasized the interplay between dispositional and situational factors, a view that had its roots in Morris Stein’s transactional creativity and Frank Barron’s ecological view (Barron, 1972; Stein, 1963). Montuori and Purser emphasized the need to uncover the philosophical, methodological, and cultural assumptions of creativity research, as it had become clear that creativity was being framed and understood differently depending on theoretical frameworks and disciplines. They also pointed to several important areas that had not been sufficiently researched, such as creative relationships, creative groups, environments that support creativity, and the creativity of women, and argued for the integration of multiple disciplinary, philosophical, and methodological perspectives in the study of creativity.

A few years later, their two-volume edited *Social Creativity* included essays by leading creativity researchers as well as philosophers, anthropologists, management theorists, and systems theorists (Montuori and Purser, 1999). There were several notable essays in that volume. Frank Barron, an early pioneer of creativity research, argued that the dominant view of creativity was a reflection of the monotheistic image of God and the seven days of creation. Barron argued that the image God the Father should be joined by the Mother, reflecting the view that *All Creation is Collaboration*, the title of his chapter (Barron, 1999). Barron saw the shift from individual creation to pro-creation or co-creation, as quite cosmic and mythical. For Barron, a shift in how creativity is understood and expressed also paralleled a shift in understanding of what it means to be human.

Mark Runco critiqued the trend in social creativity research that emphasized social judgment and “unambiguous” creators (Runco, 1999). He felt that it would draw attention away from creative potential of young people and the not-yet or never-will-be unambiguous and focus too much on what in his view is not directly relevant to understanding creativity. Along with potential, what were later to be called “everyday creativity” and “personal creativity” are not unambiguous creative achievements and may not receive significant social judgment. For Runco, *Creativity Need Not Be Social*, and social judgment is not an essential dimension of creativity.

Dean Keith Simonton compared psychology’s focus on individual genius with sociology and anthropology’s focus on the *Zeitgeist* (Simonton, 1999). He drew attention to this lesser known, sociological and anthropological research tradition in the discourse of creativity, highlighted the fundamental underlying assumptions about the unit of analysis in the different disciplines, and outlined some of the political, economic, and other factors that contribute to a creative society. It’s not just standing on the shoulders of giants, he wrote, but also rubbing shoulders with other creators, surely as good a case as any for social creativity. Volume 2 of *Social Creativity* focused on contributions in management and organization theory, disciplines which were soon to become major contributors to social creativity research and because of their focus on innovation, which is concerned with the larger process of bringing a creative idea to fruition in the marketplace.

The 21st century has seen the blossoming of the sociocultural perspective, spearheaded by the work of Vlad Glăveanu. Glăveanu developed the concept of “distributed creativity” and articulated three main paradigms in creativity research, the He, I, and We paradigms (Glăveanu, 2010, 2014). Glăveanu coined the term distributed creativity to describe creativity that did not reside inside individuals but between them, in their relationships and interactions. The He paradigm studied the traditional “lone genius,” the I paradigm individual creativity, and the We paradigm moved into the broad area of social creativity, predominantly through systems theory and the socio-cultural approach. From the socio-cultural perspective, the first explorations of social creativity still focused primarily on the individual and did not address the full potential and complexity of social creativity. Individual and social creativity were still treated as two separate worlds. A socio-cultural perspective addresses the complexity of the individual-society nexus and a more relational, contextual creativity. Writing in the introduction to the *Palgrave Handbook of Creativity and Culture Research*, Glăveanu (2016) wrote that, “culture is not an isolated factor that can be easily grouped under the general label of ‘environment’ but a *condition of possibility* for creativity” (p. 3). In other words, creativity without culture is simply not possible, and individual and culture cannot be thought of as separate. The individual is in the culture, and the culture is in the individual.

A manifesto co-authored by 20 researchers to be published in the *Journal of Creative Behavior* summarized the central assumptions of the socio-cultural approach (Glăveanu et al., In Press). A manifesto co-authored by 20 researchers and published in the *Journal of Creative Behavior* in 2019 summarized the central assumptions of the socio-cultural approach (Glăveanu et al., 2019). They include but are not limited to the view that creativity is a multidimensional phenomenon, at once psychological, social, and material (physical and embodied), and it involves culturally mediated action. Creative action is at all times relational. Creativity research needs to consider power dynamics both within its analyses and as a field of study. Central to this approach is a critique of the traditional view of the individual and the social as two distinct and separable units. Izabela Lebeda and Glăveanu (2019) Glăveanu and Izabela Lebeda (2019), are the co-editors of the *Handbook of Social Creativity Research*, a volume that brings together the state of the art in this rapidly expanding field, and reflects the growing interest that in social creativity over the last 20 years.

Harking back to Runco's original concerns, the emergence of social creativity and the We-paradigm has led some psychologists to argue for a more focused approach, one that is parsimonious and addresses what they feel is strictly necessary for creativity, its *sine qua non*, which they refer to as the "mechanism" of creativity. This would eliminate bringing in topics that in their view are not directly relevant like social judgment or personality. This approach also brings creativity research squarely back into the psychologists' fold, rather than having it fragmented in a multiplicity of disciplines. An alternative proposal views transdisciplinarity as a way to integrate the voluminous creativity research currently being generated in multiple disciplines, not primarily for the purpose of creating grand theories, although that is not excluded, but for application to specific issues, connecting theory and practice, and bringing the research to bear on a world in need of creative approaches to vexing problems (Montuori, 2018).

Historical and Intellectual Context

The concept of creativity as it is known in the West today can be traced back to the Renaissance, coinciding with the birth of humanism and individualism. It blossomed with the *genius myth* that emerged with Romanticism in the late 18th century. Assumptions about creativity established during the Renaissance, Romanticism, and the Industrial Revolution, continued to shape the cultural imaginary and the academic study of the phenomenon. Until the 1980s, research on creativity in the West was situated mostly in the discipline of psychology and focused primarily on what were known as the four Ps: person, process, product and press). The unit of analysis was almost exclusively the exceptional or "eminent" individual. The romantic mythology created an "atomistic" view, which holds that even complex social phenomena can be traced back to the primacy of the individual, and the social and society are merely an accumulation of individuals. A lasting legacy of this view was that the creative person was mostly a lone, often eccentric, genius, and always white and male.

In the dominant four P's model, the *who* of creativity was a *person*, and was therefore by definition limited to an individual. Groups, organizations, cultures, and relationships were not included, and in fact popularly depicted as representatives of conformity and compliance, and mostly viewed as potential obstacles for the creative person. The genius or more generally the creative person was viewed as being in an oppositional relationship with other people and more generally with society. The social was pitted against the individual. This view is characterized in the popular imagination by such works as novelist Ayn Rand's popular book *The Fountainhead*, also made into a movie in 1949 starring Gary Cooper, which depicted the struggles of a headstrong creative architect unwilling to compromise in the face of an onslaught of demands for conformity and mediocrity. Popular movies about highly creative individuals, such as *Bird*, *Amadeus*, and *Immortal Beloved*, focused on misunderstood, tragic genius figures (Charlie Parker, Mozart, and Beethoven) struggling with an often hostile social environment. These images reflected and in turn fed into the mythology of the genius battling with recalcitrant, conformist, jealous, and often cruel others, as in the highly fictionalized relationship between Mozart and Salieri in *Amadeus*. Another view is that creativity is a "gift" the genius possesses and so it does not require any work, which in the case of Parker, for instance, glaringly omitted the less photogenic years he claimed to have practiced 8–10 hours a day.

A number of intellectual and social developments in the late 20th and early 21st century have questioned the foundations of Western thought. They directly or indirectly led to questioning, critiquing, and proposing alternatives to the dominant individual-centered approach to creativity.

- Psychologists with a social constructionist orientation as well as sociologists have argued that who or what we call "creative" is the result of a social judgment, and that creativity is therefore socially constructed and does not exist "naturally," independently of that judgment.
- Authors in the movement loosely known as postmodernism have critiqued the notion of the autonomous individual. They proclaimed the death of the "subject" and the "author," and ushered in "the birth of the reader." This involves foregrounding readers' individual interpretations and rejecting the dominant role of the author. They also stressed the commercial and political interests and power dynamics embedded in the discourse of creativity. Postmodern thinkers criticized the image of the genius, and the notion of originality, discussing the role of "bricolage," the combining and recombining of existing materials, summarized in the expression "everything is a remix."
- From the perspective of systems and complexity theories creativity research has viewed individuals as closed systems, unaffected by their context. An open system approach situates individuals in their social context and in a network of

relationships. The self-organization and emergence of natural and social phenomena attracted attention, as did the role of “swarms,” with a bottom-up, distributed, rather than top-down approach, stressing the significance of recursive, mutually causal interactions.

- Researchers studying the psychology and creativity of women have argued that the creativity of women cannot be assessed without taking into account social and cultural factors. Women were portrayed as fundamentally not creative in the same way as men are, and through much of history women were not allowed to participate in those very domains in which one would be recognized as creative.
- Cultural psychology is an interdisciplinary field that draws on a wide variety of disciplines including anthropology, neuroscience, cultural studies, and the philosophy of mind. For cultural psychology, mind and culture are not only inseparable but mutually constitutive. Minds shape culture and culture shapes minds, and the emphasis is on studying the nature of this process.
- Management and organization theorists have developed an interest in creativity as part of the larger process of innovation. Whereas the creative process has traditionally been viewed as something that goes on inside an individual and leads to the proverbial lightbulb going on, the process of innovation includes idea generation but is much more extended in time and space. Idea generation is important, but part of larger process that goes all the way to implementation and is therefore by its very nature a more social process.

These are but some of the intellectual trends and developments that have contributed to research in social creativity. It should be pointed out that the focus on the individual creator and the genius has also, ironically, become a marketing tool that reflects the deeply interwoven nature of individual and society. The relatively recent focus on social creativity also parallels the fact that post baby-boom generations seem to be less interested in genius, and more in everyday and relational creativity.

Women and Creativity

The history of women and creativity provides an important entry point into the relevance of social creativity. Historically much if not most creativity research has been about eminent white males in the West. As a result, the picture that was first developed about creativity, the creative person, and the creative process, is based on a sample that was almost exclusively white and male. Eysenck (Eysenck, 1995) summarized the effect of this sample with the following conclusion: “Creativity, particularly at the highest level, is closely related to gender; almost without exception, genius is found only in males (for whatever reason!)” (p. 127).

It is perhaps not surprising that Eysenck should conclude with “for whatever reason.” While in 1995 there was already considerable research on the historical struggles of women in the arts and the sciences, the topic was only beginning to attract interest in psychology. Given the fundamental attribution error, it might be tempting to seek the reason for women’s under-representation in the lists of great creators to their personalities or cognitive processes or even genetics. Feminist scholars have argued for years that for most of recorded history women were not given full access to the domains in which creativity could be demonstrated (the arts and the sciences). In Europe and the USA women were not allowed to practice drawing nudes, give concerts in public, go to medical school, and study science until the middle of the 19th century. These social factors clearly inhibited the creative potential of women, and the perspective of historians and sociologists contributes to a broader picture, addressing aspects of women’s lives that psychologists generally do not address. The argument has also been made that the discourse of genius and creativity is shaped by male-centered or even patriarchal approaches which started out with the assumption that, broadly speaking, men are creative and women make babies.

But does the fact that women had no access to socially recognized domains of creativity (major artworks, scientific breakthroughs, etc.) mean that they had no opportunity to be creative in Europe and the USA until the 20th century and therefore were simply not creative for millennia? Or merely that working within the social limitations, the definition of the what, who, where, and how of creativity was preventing an understanding how the creativity of women was manifesting? Is it the case that, despite their lack of access to traditionally accepted domains of creativity, women are simply not as creative as men? This does not appear to be the case.

Perhaps it is necessary to redefine creativity through an articulation of a more relational perspective and highlight the many ways in which women have been creative in different contexts and different ways (Eisler et al., 2016). Examples include areas that have traditionally been seen as women’s domains, in the home, child-rearing, and in such private, domestic activities as improvising meals for the family rather than in more public, dramatic ways such as becoming celebrated chefs. The creativity of women, while initially excluded from the arts and sciences, has therefore historically manifested in what today might be considered more social, more relational, and more *everyday* activities, as opposed to socially recognized creativity. In that sense, the new interest in *everyday, everyone, everywhere* creativity is prefigured in the creativity of women, meaning more specifically the areas in which women could express their creativity. This should not be interpreted to mean that these are the only areas where women can or should be creative, of course, simply that given the social restrictions, articulated so well in Virginia Woolf’s *A Room of One’s Own*, women were in fact being creative during the centuries they could not participate in the domains where eminent creativity was recognized, but in domains and ways that were not as yet recognized in the research literature or socially acknowledged.

Ravenna Helson (1990) wrote that

We think the understanding of creativity in women requires attention to the social world, to individual differences in motivation and early object relations, and to changes in society and the individual over time. In fact, we believe that the study of creativity in general needs all of these directions of attention (p. 57).

The reasons for Helson's argument for a more social approach are clear and not just confined to an understanding of historical obstacles. In the last 50 years considerable changes have seen many more women become prominent in the arts and the sciences and join the rank of Nobel prize winners. Nevertheless, in the early 21st century, research found that girls and boys are taught science differently, it is still difficult for women to break into certain disciplines, and Silicon Valley, a center of tremendous innovation, is criticized for being a "brotopia" that excludes women. What Helson is pointing to is the need for an approach that draws on multiple disciplines and recognizes the pervasive role of culture in shaping young women, their choices and opportunities, as well as the way the cultures of organizations and universities can exclude women. Along with understanding how women have been excluded from creative endeavors, it is also important to explore how a better understanding of women's creativity might broaden our understanding of creativity as a whole. Social creativity is beginning the exploration of a more relational approach to creativity.

Philosophical and Disciplinary Considerations

The emergence of social creativity brought focused attention to the way in which researchers create their understanding of and approach to creativity. As a result it has raised numerous complex and important issues that can be traced to ongoing debates in philosophy and specifically the philosophy of social science, as well as the role of disciplines in framing questions and entire subject areas.

The interest in social creativity has shown how different disciplinary perspectives and different underlying philosophical and cultural assumptions can lead to very different perspectives on creativity. In the philosophy of social science, the different perspectives broadly underlying psychology and sociology are sometimes referred to as atomism and holism, or more specifically methodological individualism and methodological holism respectively. If atomists argue for the primacy of the part and the fictitious nature of the whole, as in Mrs Thatcher's famous statement that there is no such thing as society, holists argue for the primacy of the whole over the part. A key difference between psychology and sociology is precisely the choice they make about whether to foreground the part or the whole. This choice determines the *unit of analysis*. Psychologists have historically viewed creativity as the result of dispositional characteristics, processes, and properties of individuals. For the vast majority of psychologists, the individual is therefore the unit of analysis. Sociologists and anthropologists have viewed creativity more as a function of social structures and processes, and the *Zeitgeist* or spirit of the times, therefore situationally.

For methodological individualists in creativity research, the focus on the individual also means that whatever is outside the individual is essentially *epiphenomenal*, or not causally affecting the phenomenon in question. In this view it is not necessary to include factors that are considered epiphenomenal in order to gain a full understanding of creativity, and it has been argued that any attempt to include complex factors such as culture would simply be too daunting. The implications have been considerable, and not limited to making the research process more manageable. With methodological individualism the dominant approach in American creativity research, it is not surprising that creative collaborations, group creativity, the study of creative cities and epochs and generally of environments that foster or hinder creativity have historically received less attention, with some notable exceptions.

For methodological holists it is individuals who are epiphenomenal. Specific individuals are merely vehicles for ideas that are part of the *Zeitgeist*, or ideas that are "in the air." This is not a mystical phenomenon but usually simply the result of an accumulation of developments in a particular field leading to a situation where it is almost inevitable that someone will take the next logical step. The phenomenon of "multiples," when two or more scientists come up with the same idea—Darwin and Wallace with evolution, for instance—is often used as an example. The role of networks connecting schools of thought and tracing lineages of philosophers and social scientists, has also begun to play a role in the understanding of creativity in the history of ideas.

The underlying philosophical assumptions of the two major perspectives on creativity have further differences. Using rather broad generalizations, it has been argued that the psychological, individualistic approach is also fundamentally *idealistic* in the sense that it focuses largely on the generation of creative ideas, but no systematic attention is paid to how those ideas can become a reality. Idealist philosophy is more interested in the idea rather than its physical manifestation. An idealist aesthetics holds that the score of a musical composition is an ideal which can only be approximated by a performance because it is closer to what the composer had in mind, and subject to less translation and interpretation. This is arguably the view of psychologists who want to decouple creativity from the social, by eliminating the term "useful" from the definition. What is essential for them is the generation of creative ideas, and specifically the mechanism whereby ideas are generated. They are less or not interested at all in the implementation.

Sociologists, and particularly sociologists of work, have brought a different perspective to the table, namely a more *materialist* philosophy. This is evident in their close study of what it actually means to work in professions such as the arts and put on a jazz performance, get a motion picture into the theaters, a novel into bookstores, and so on. The sociologist Howard Becker listed the credits of a motion picture to give an idea of the enormous collective effort that is required to bring a movie in front of the public. The same is true for a musical recording, getting a book from the author's desk to the bookstore, and even a school production of a musical. To attribute the creation of a motion picture, the performance of a jazz group, or the design of a fashion item to

one individual simply overestimates the importance of the individual and does not recognize the contribution of others. The romantic mythology of the creator as lone genius takes a back seat to the network of relationships necessary to take any creative idea into the world.

Key differences between the two approaches are in the definition and scope of the creative process. Can the creative process be reduced to the essential moment the light-bulb goes on, or is it a process that can be traced beyond the individual, perhaps as far back as the education and preparation preceding the idea(s), and then all the way to implementation, bringing a product to market or a concert performance of a composition? The sociological approach has broadened the understanding of creativity to the extent that it tells us about how an idea becomes a reality, and clearly this is an extremely important dimension of the process. A greater understanding of the process by which creative ideas become realities can also help create environments and systems that facilitate creativity. Where we draw the boundary around what constitutes the creative process is a function of the researcher's disciplinary and philosophical perspective. Systems theorists refer to this as the system definition, essentially what is in and what is out of the scope of any inquiry. One view sees the creative process as confined to the generation of the idea, for the other it extend to include the entire production of a movie, including the script writing, editing, and all the support functions from the technical to the logistical. This difference exemplifies the different definitions of creativity and innovation, idealist and materialist respectively, but it also reflects different angles on a large and complex phenomenon, each offering insights that reflect a different facet.

Are these contrasting views of the who and how of creativity opposed, incompatible, or complementary? Or would the relationship best be described by saying ... it's complicated? The history of social science is full of oppositions and polarizations, with schools of thought and disciplines identifying themselves in opposition to each other. The disciplinary split between psychology and sociology is one example, showing up as the lone genius versus the zeitgeist, but also individual agency versus sociological determinism.

The problem of disciplinary fragmentation means that researchers in one discipline may be carrying on their own research agenda with assumptions and theoretical frameworks that are diametrically opposed to those in the discipline next door, which might as well be a universe next door, often blissfully unaware of what their neighbors are doing. If each discipline or subdiscipline believes it has the right (and most legitimate or scientific) approach to creativity, then researchers may choose to ignore each other or argue against other perspectives. While debate and critique are healthy, it is a sad fact that exchanges among academics are often critical rather than creative, as captured in statements like "I defended my position," "she destroyed his argument." Arguments over intellectual territory are not unusual but attempts to create across disciplines can be few and far between.

How to address this often conflicting proliferation of research, disciplines, and assumptions? Most academics do not receive training in integrating knowledge across disciplines, or in how to be socially creative in the study of creativity. A key challenge for creativity researchers today, during a historical moment when creativity is needed more than ever, is to connect across disciplines and across cultures to put creativity research to work. While increasing specialization is a given for academia, social creativity points to the need to be able to integrate complex ideas and pertinent findings across different disciplines and each with different fundamental assumptions, a task which itself requires social creativity. In that sense, the criticism that social creativity is too complex, and researchers would be better off working with clearly delineated closed systems that are all within their specific area of competence is perhaps legitimate, given the current state of affairs. But one of the most exciting aspects of social creativity research is precisely that, by its very demands, it may usher in a new and more complex, transdisciplinary approach to creativity.

Conclusion

The broad umbrella of social creativity has drawn attention to and created a space for research in topics such as creative relationships and groups that had largely been ignored until the 1990s. It has also led to philosophical questions and debates about the nature of the individual, the relationship between individual and society, and the nature of creativity. Social creativity has also begun to explore how creativity research itself has been created, through the way it is represented in popular culture, with implicit folk beliefs about creativity, and by creativity researchers themselves, who are themselves not immune to the influences of their own culture. Increasingly, researchers are approaching creativity from a multiplicity of disciplines and perspectives. Understanding social creativity requires this rich multiplicity of views and thereby makes new demands of researchers to expand their scope and become inter- or even transdisciplinary. Social creativity may succeed in articulating the centrality of creativity in society and social change processes, thereby bringing creativity to the forefront of social research.

Glossary

Causal analysis Identification of the causes operating in complex systems.

Constraint analysis Identification of conditions that bound, or limit, solutions.

Creative thinking skills Processing activities by which people work with knowledge to produce new ideas or problem solutions.

Forecasting Projecting the downstream implications of actions.

Institutions Social systems characterized by people, norms, and expectations.

Planning Envisioning actions needed to accomplish a task.

Social innovation Creative solutions to social problems.

Wisdom Appraisal of the value of actions in a social context.

Social Innovation

The most common image of a creative person is of an individual working alone, who produces a unique product of exceptional value. Thus, artists are seen as creative. Scientists are seen as creative. Composers are seen as creative. Although this entry does not dispute the creativity required for eminent achievement in the arts and sciences, the argument will be made that the notion that creativity involves only individual production is, in fact, misleading.

Creativity has been defined as the production of original, high-quality, and elegant solutions to complex, novel, ill-defined problems. At times complex, novel, ill-defined problems cannot be solved by a single person working alone. Accordingly, many research studies have examined how teams go about solving creative problems, how creative teams should be led, and how institutions should support creative efforts.

Not only does the social context shape the nature and success of creative work, the social context in which human activities occur also presents many complex, novel, ill-defined, or poorly structured problems—problems that cannot be solved simply through norms or routines. Traditionally, the solutions of complex, novel, ill-defined problems which arise in an institutional, or social, context are the responsibility of leaders. And, in fact, creative thinking is a crucial determinant of leader performance. However, the solution of institutional problems may come from many sources, entrepreneurs, activists, and even politicians, and it is the solution of novel, complex, ill-defined problems arising in an institutional context that defines what is meant by the term social innovation.

Case Studies

Even the most cursory review of history suggests social innovation plays an essential role in human progress. Much of modern life occurs in industrial institutions, business firms, and these firms clearly depend on social innovation. One key basis of the modern firm is the concept of standard operating procedures. It was Frederick Taylor who had the idea of posting standard operating procedures on lathes in a machine shop. Modern industrial institutions also depend on mass production procedures. And, as Mumford and Moertl (2003) noted, mass production ultimately was based on an innovative solution to a distinctly social problem—a solution which initiated a chain of other social and technical innovations.

Social innovation is often critical in politics. One example may be found in Lyndon Johnson's establishment of the Equal Employment Opportunity Commission as a way of reducing discrimination in United States firms. Advances in city planning and human housing can be traced to social innovations advocated by Robert Moses and Jane Jacobs. The work of many social advocacy institutions, for example, the United Way, Doctors Without Borders, or Alcoholics Anonymous, all are based on social innovations.

Mumford (2002) conducted a qualitative study of one historically notable social innovator, Benjamin Franklin, in part because he left firsthand accounts of multiple social innovations he developed in a fixed social environment—colonial Philadelphia. These ten historically noteworthy innovations included establishing paper currency, establishing the first nonsectarian university, and creating volunteer fire departments. A review of these cases indicated, first, that social innovation required creative thinking skills as traditionally defined and, second, a complex set of unique skills, tied expressly to social innovation, such as causal analysis, forecasting, and wisdom.

Creative Thinking Skills

Mumford et al. (2012) described what has become the standard model of creative thinking. They argued creative problem solutions require knowledge, or expertise, along with successful execution of a series of eight cognitive processes for transforming extant knowledge into viable, original, high-quality, and elegant problem solutions: (1) problem definition, (2) information gathering, (3) concept/case selection, (4) conceptual combination, (5) idea generation, (6) idea evaluation, (7) implementation planning, and (8) adaptive monitoring. In fact, an examination of the careers of social innovators, Benjamin Franklin and Jane Jacobs, indicates they had acquired substantial expertise with regard to the social problem at hand—Jacobs was an architectural critic; Franklin routinely reported on fires in Philadelphia. The evidence accrued in recent years, moreover, indicates that effective execution of all of these cognitive processing operations are also critical to solving social innovation problems.

Conceptual combination, combination and reorganization of extant knowledge structures, provides the basis for establishing the new knowledge structures that allow people to formulate viable new ideas. Scott et al. (2005) showed that skill in conceptual combination also contributes to performance in solving social innovation problems. In this study, participants were asked to formulate a curriculum plan for a new experimental secondary school, a social institution, where judges appraised solutions for quality, originality, and elegance. Participants were instructed to use various strategies in conceptual combination where concepts, or cases, were presented. It was found effective execution of these conceptual combination strategies resulted in the production of more original, higher quality, and more elegant curriculum plans.

In another study along these lines, Redmond et al. (1993) examined peoples' performance in solving another type of social innovation problem—a marketing problem. Participants' marketing plans were appraised by marketing professionals for quality and originality. Notably, a manipulation was induced to encourage better problem definition. This manipulation asked, or did not ask, participants to write down key issues and concerns and define the problem in their own terms before formulating their marketing campaigns for a new product—the 3D Holographic TV. It was found that those who were exposed to this problem definition manipulation produced solutions of higher originality and greater quality to this social innovation problem.

In another study, Gibson and Mumford (2013) asked participants to formulate a plan for a firm which intended to extend its product line into a new region or new market—a different cultural market. Plans were appraised by judges for quality, originality, and elegance. Notably, idea evaluation was examined by asking participants to criticize candidate campaign ideas before starting work on their own campaigns. Evaluations of these ideas indicated participants who produced a limited number of deep criticisms developed stronger, more original, higher quality, and more elegant, solutions to this social innovation problem.

The foregoing studies indicate conceptual combination, problem definition, and idea evaluation, three key creative thinking processes, influence peoples' ability to produce viable solutions to social innovation problems. When this observation is considered in light of other studies demonstrating that effective execution of other creative thinking processes contributed to the solution of social innovation problems, it seems reasonable to conclude that standard creative thinking skills are, in fact, needed to solve social innovation problems. However, it appears, due to their unique nature, social innovation problems may require a broader array of skills.

Causal Analysis

In institutions, or social systems, the causes of a problem are not evident, and many causes operate. Thus, to solve social innovation problems people must be able to identify critical causes. The impact of causal analysis skill in solving social innovation problems has been examined in a series of studies by Hester et al. (2012) and Marcy and Mumford (2007). In these studies, participants were asked to complete, or not complete, a set of self-paced training modules intended to improve their causal analysis skills: thinking about causes that (1) have large effects, (2) have direct effects, (3) are controllable, (4) can be manipulated, (5) effect multiple outcomes, (6) operate synergistically, and (7) work together.

In the Marcy and Mumford (2007) study, participants were asked to solve six social innovation problems, three drawn from the educational domain and three drawn from the business domain, where judges appraised solutions for originality and quality. In another study, participants were asked to work on a simulation exercise with the objective of improving teaching at a university

where performance was appraised using objective markers of game performance. In a study by [Hester et al. \(2012\)](#), participants were asked to formulate a marketing campaign for a new high-energy root beer where judges appraised solutions for quality, originality, and elegance. These studies indicated that training in causal analysis skills resulted in production of solutions of higher quality, originality, and elegance, better exercise performance, and, additionally, stronger mental models for understanding social innovation problems. Thus, causal analysis skills apparently contributed to social innovation.

Constraint Analysis

Social innovation problems are always constrained by people's vested interests and prior capital investments. Thus, solutions to social innovation problems must be formulated within a set of social constraints ([Medeiros et al., 2014](#)). Indeed, finding ways to work around constraints may be critical to solving social innovation problems. The impact of constraint analysis skills on social innovation was demonstrated in a study by [Peterson et al. \(2013\)](#).

In this study, participants were asked to formulate a curriculum plan for leading a new experimental secondary school. Judges appraised plans for quality, originality, and elegance. Before starting work, participants were asked to illustrate their mental model for understanding secondary school performance and, again, illustrate their mental model after completing all study activities. In between, however, prior to starting work on their solutions to this social innovation problem, participants were asked, or were not asked, to complete a series of four self-paced instructional modules to help them analyze constraints: (1) resources constraints, (2) system capability constraints, (3) user skill constraints, and (4) goal constraints. Findings indicated that this instruction in constraint analysis resulted in higher quality, more original, and more elegant solutions to this social innovation problem as well as acquisition of better mental models for understanding the problem.

Planning

Social innovation problems differ from other problems in that multiple people must be marshalled, or organized, to act on various causes and constraints. This rather straightforward observation implies planning skills will also be required to solve social innovation problems. Some rather compelling support for this proposition was provided in a study by [Marta et al. \(2005\)](#). In this study, 55 teams were asked to formulate a "turn around" plan for a failing automotive firm where failure was due to a host of socio-technical issues. Judges appraised the quality and originality of the resulting turn around plans. After teams had formulated their plans, they were asked to nominate their leader. And, all participants, regardless of leadership role, were asked to complete a measure of planning skills.

The planning skills measure presented a series of institutional planning scenarios where participants were asked to select responses marking differing levels of various planning skills. The highest quality and most original "turn around" plans were produced by teams whose leaders evidenced strong planning skills. Other studies showed that training people in key planning skills, by providing appropriate planning strategies, resulted in production of higher quality and more original solutions to social innovation problems.

Forecasting

Plans sometimes work out and sometimes do not. Forecasting the outcomes of a plan execution allows people to anticipate the downstream implications and provides a basis for revision of the plan if needed. In fact, viable forecasts may allow people to formulate actions to address the kind of roadblocks that emerge in many social innovation efforts. Although it seems reasonable to conclude forecasting is critical to social innovation, peoples' ability to forecast effectively has been questioned.

In a study, participants were asked to assume the role of a member of a funding agency's proposal review board. They were asked to review three educational proposals or three public policy proposals—all social innovation problems. Both the education and public policy proposals had actually been executed, so resource requirements and outcomes were known. As a member of this review panel, participants were asked to estimate, or forecast, resource requirements and outcomes. It was found these forecasts could be quite accurate, within a fifth of a standard deviation, at least when participants had expertise and believed their recommendations would be acted upon ([Dailey and Mumford, 2006](#)).

If people can forecast accurately, the next question is whether forecasting contributes to performance in solving social innovation problems. A study asked participants to formulate a marketing campaign for a high-energy root beer ([Byrne et al., 2010](#)), while in a related study, participants were asked to formulate a curriculum plan for leading a new experimental secondary school ([Shipman et al., 2010](#)). The marketing and school plans were appraised by judges for quality, originality, and elegance.

As participants worked on each of these low-fidelity simulation tasks, prior to plan production, they received a series of emails, from consulting firms or their managers, where they were asked to forecast the implications of executing their ideas. Judges appraised these written forecasts and four general dimensions emerged: (1) forecasting extensiveness, (2) forecasting time frame, (3) forecasting resources, and (4) forecasting negative outcomes. More centrally, it was found that the extensiveness of forecasting and forecasting a longer time frame were strongly ($R \approx 0.40$) positively related to the production of higher quality, more original,

and more elegant solutions to both social innovation problems. Indeed, the prediction of performance vis-à-vis forecasting was, in fact, stronger than traditional ability measures such as intelligence and divergent thinking. Thus, forecasting, especially extensive forecasting, considering multiple alternative scenarios, seems critical to peoples' success in solving social innovation problems.

Wisdom

Extensive forecasting will lead to the production of multiple, varied, outcomes as a result of planned actions. These forecasts will have different impacts on different stakeholders. Thus, in social innovation, people must be able to appraise how their anticipated actions will affect various stakeholders. Put differently, viable solutions to social innovation problems require wisdom. In fact, it has been argued that wisdom is a critical skill for solving many types of creative problems, especially social innovation problems.

Some rather compelling support was provided in a study by [Connelly et al. \(2000\)](#). A sizable sample of Army officers, some 1800, ranging in grade from Second Lieutenant to full Colonel, were asked to describe their performance in addressing critical incidents encountered over the course of their career—incidents appraised by judges for performance effectiveness. In addition, they were asked to solve a social innovation problem dealing with reorganization of the Army into a regimental structure. These officers were also presented with a series of complex ambiguous problem scenarios describing events in the life of middle managers. Officers were asked to provide written answers to three questions: (1) Why did this situation occur? (2) What was the mistake made in this situation? and (3) What would you do if you were in this situation?

Trained judges with expertise in psychology appraised written answers to these questions for dimensions held to underlie wisdom such as systems perception, objectivity, sensitivity to solution fit, judgment under uncertainty, self-reflection, and systems commitment. When performance on the social innovation problem and critical incident performance were correlated with, and regressed on, these attributes of wisdom multiple correlations in the 0.40 s were obtained for both the social innovation problem and critical incident performance. Thus, wisdom contributes to performance, “real-world” performance, perhaps because it is a critical skill which allows military officers, to solve the social innovation problems institutions expect them to address.

Conclusions

This entry reviewed studies which are noteworthy because they suggest wisdom, forecasting, planning, constraint analysis, and causal analysis all contribute to peoples' ability to solve social innovation problems. These abilities work along with traditional creative thinking skills (conceptual combination, problem definition, and idea evaluation) traditionally held to contribute to creative problem-solving across a number of domains. Thus, solving social innovation problems may be a particularly complex activity requiring both creative thinking skills and special skills uniquely related to solving social innovation problems. Although solving social innovation problems represents an especially complex activity, it should also be recognized that many studies of social innovation, for example [Marcy and Mumford \(2007\)](#), indicated that these skills, causal analysis, constraints analysis, and wisdom, can be developed. Given the complex nature of social institutions, and the real-world value of solving the social innovation problems presented by these institutions, there would seem to be ample justification for systematic interventions intended to develop these social innovation skills.

Introduction

Change is urgently needed in human society. Longstanding problems such as hunger, poverty, and armed conflict resist even the best efforts to solve them. Industrial capitalism (with its focus on producing more and more objects of consumption) has been taken beyond survivable limits. Tribalism, racism, and misogyny have increased, with the help of modern technologies. Fortunately, visionaries with imagination and resourcefulness are working in transformative new ways to tackle these problems.

- Rats are trained to detect buried explosive mines in former war zones and to indicate their location to their handlers; human teams then more safely clear the mines.
- Homeless people are taught beekeeping skills, which simultaneously addresses homelessness and the falling numbers of our most important pollinators.
- Temporary “popup” repair shops offer free or low-cost repairs of household objects and appliances, keeping them out of landfills and reducing the use of resources to make and market new ones.

According to Bulut et al. (2013), *social innovation* is a relatively new term. For this article, we will use Phills, Deiglmeier, and Miller’s definition (quoted in Bulut et al., 2013, p. 437): “Social innovation refers to a novel solution to a social problem that is more effective, efficient, sustainable, or just than actual solutions, and for which the value created accrues primarily to society as a whole rather than private individuals.”

Of course, it is possible for social change to move toward violence, greed, and prejudice. Social media, for instance, in addition to encouraging justice and building useful networks, have stoked hatred and spread falsehoods, divisiveness, and violence. This article, however, focuses on positive innovations that support ecosystems, justice, health, and equality of opportunity. In recent decades, new services and tools have been invented to help people collaborate, even at a distance.

- Pooling funds from hundreds of people to “kickstart” a worthy project, bypassing traditional funding gatekeepers.
- Citizen science, when amateur enthusiasts contribute to genuine research,
- Community Supported Agriculture, which links farmers directly to their customers.

Meanwhile, in some cases individuals have invented solutions with minimal outside support.

- Shoes designed to enlarge along with the growing child, reducing child-rearing costs for the poor.
- Planting live trees to make corrals to protect cattle from marauding lions (and lions from irate herders),
- A functional bicycle made out of cardboard.

Some of these innovations have received academic evaluations, which are noted here. By the nature of this topic – recent inventions – some have not. Perhaps not all of these inventions (and others described below) will stand the test of time, but the sheer

profusion of resourceful ideas offers evidence that people of all ages, nations, races, and classes are facing our problems with ingenuity and hope.

Definitions

Creativity in this context means innovation with an explicit goal to solve a real-world problem, such as hunger, war, disease, extinctions, and environmental destruction. Creativity is difficult to define according to some authorities (Acar et al., 2017) but not others (Runco and Jaeger, 2012). Commonly studied factors are originality and practical value.

Environmental problems. Human activities (including overpopulation) that overuse or destroy resources, or cause degradation of ecosystems, leading to climate change and (among other things) species extinctions beyond the background rate caused by natural processes.

Social change. The purposeful alteration of conditions, processes, laws, and customs. *Social transformation* involves larger changes, deeper insight, questioning of assumptions, originality of solutions, and the expectation that deleterious unintended consequences should be minimized. All stakeholders are, as far as possible, taken into account, and the circular economy (also called cradle-to-cradle; McDonough and Braungart, 2002) eliminates the concept of waste.

Social innovation. A non-physical creation that involves connection, networking, and in some cases the use of technology to address a problem. Examples include distance learning, hospice, restorative justice, congestion charges to modify traffic, open source software, and microcredit (Jiang and Thaggard, 2014).

Social problem. Conditions that cause unnecessary pain, destruction, or waste. "Unnecessary" because some pain is inevitable, such as the death of a loved one. "Waste" because earth's abundance is not unlimited, and we are consuming ourselves out of house and planet. Waste can include waste of people, as through drugs and the prison-industrial complex, and underutilization of people through poor education, biases, or cultural traditions.

Why Creativity Is Needed

Given the severity of the global problems that humans have created, we must act promptly. Familiar strategies for change (strikes, boycotts, education, legislation, court decisions, support groups) are valuable, but insufficient, for several reasons (Riebel, 2015, 2017):

- Usual solutions are *too slow*.
- Many of the problems are *interlinked*.
- Solutions must require *less extraction of natural and human resources*.
- Solutions must *take all people into account*.
- *Psychological defense mechanisms* protect many people from seeing and tackling the problems.
- *Political will* is needed to overcome defense mechanisms, entrenched opposition, vested interests, and inertia.

Creativity Is Already in Use

The range of social-change creativity is impressive. The people involved range from highly educated to barely literate; urban to rural; young to old; first-world to third-world. The domains include agriculture, food waste, endangered species, healthy exercise, packaging, refugees, street children, waterborne illnesses, organ donations, and dozens more. Innovations are being devised by individuals, pairs, small groups, large groups, governments, and corporations. There is serious academic interest in creative social change, as attested by the growing number of departments, courses, degrees, and dissertations.

Creativity has been tied to everything from artistic achievement to entrepreneurship to cultural evolution. It may very well represent one of the most basic and important human capacities, as evidenced by its role in so many and such diverse domains and endeavors.

Runco and Kim (2011, p. 534)

Domains and Applications

By definition, the creative acts described in this article are of practical use, incomplete until they reach production and distribution, helping solve social and environmental problems. This accords well with Simonton's view (quoted in Allen and Thomas, 2011, p. 114) that "creativity requires persuasion and social influence. In other words, a creative act can only be fully creative if it reaches an audience."

The cornucopia of inventions both physical and social in the last few decades demonstrates creative thinking at work. Some of them undo our previous errors of waste and destruction, such as using biodegradable flexible rings to join 6-packs of beverages, thereby reducing threats to wildlife. Some advance primal needs: a large drum made of industrial plastic can be wheeled along the ground, efficiently moving large quantities of water. Some solve several problems at once: offering free housing to university

students who provide companionship and help to elders in nursing homes. Some are quirky: an advocate for bees runs races backwards to draw attention to the serious threats facing these vital pollinators. Some re-envision society: the Soccket captures kinetic energy in soccer balls to provide electricity, harvesting the value of the simplest human motions. Some recapture traditions: A Zuni map project enlists elders, leaders, and artists at the A:shiwi A:wan Museum and Heritage Center in New Mexico to reclaim the Zunis' understanding of land and place. Instead of mathematical coordinates and Anglo or Spanish place names, the maps commissioned by the project display natural features, traditional creation and migration stories, native names, and colorful paintings.

Some inventions are created by developers who are trained professionals in the relevant field and some are developed by amateurs. Some are physical inventions, and some are social innovations, some of which employ technology to link people together efficiently.

High Tech Versus Low Tech

Of the various dimensions that characterize creativity and social change, one of the most significant is the degree of technology required to develop an invention and make it available to end users.

Low tech. Using existing or easily fabricated objects, people have devised solutions to various challenges. In 1970 when an explosion aboard the Apollo 13 spacecraft endangered the lives of the astronauts, a team on the ground had to instantly invent a way to connect two incompatible machines to clear the air of life-threatening levels of carbon dioxide, using objects that they knew were already on board the craft.

They succeeded, and members of the most sophisticated, complex, high-tech mission ever attempted were saved by scissors, duct tape, cardboard torn from a manual, hoses used for emergencies, and plastic tubing from a moonwalk garment.

Advantages of low tech. Aside from such dramatic rescues, in poorer countries without modern infrastructure, power and water can be made available using low-tech devices like the LifeStraw water purifiers and a simple gadget that generates light by harnessing gravity. Such innovations usually involve less waste and require less time to install.

High tech. The tiny house movement is meant to provide shelter for poor and homeless individuals, or for people wanting or needing to live lightly. Often these are relatively basic structures, but a Slovakian company builds high-tech ones (Ecocapsules) for the more affluent, equipped with solar power, wind turbine, rainwater collection, computer monitoring of electricity and water use, and more. The ecocapsule, which is easily moved, could help solve housing shortages that occur even in prosperous societies.

Advantages of high tech. For some applications, basic elements already exist. Cell phones can help remote inland farmers bypass profit-taking middlemen, learn the true value of their goods, and receive fairer compensation. Additionally, cell phones leapfrog over costly 20th-century infrastructure (miles of telephone lines), making the delay and cost of installing the latter unnecessary. In Tasmania, “virtual fences” – small light- and sound-emitting devices installed along roadways – have drastically reduced the number of mammals killed by automobiles.

Domains

Any domain of life has potential for creative individuals to introduce improvements: food, housing, energy, environment, community, animals, waste, health, safety, transportation, and more. Some solutions address multiple domains at once, e.g., food and waste, or energy and environment. Consider conflicts between humans and wildlife, as in the following example of protecting people and animals from each other.

Farmers play “crops and robbers” as they work to protect their harvests from insects, birds, and other hungry wild animals – including the largest ones. Elephants and tigers are among the land mammals most involved in conflict with human farmers, who often kill them. Defenders of wildlife look for solutions, especially multiple approaches that can be used in rotation to prevent animals from habituating to them. Scientists knew that elephants fear and avoid bees, which can sting their sensitive eyes and trunks. In her doctoral dissertation, King played recorded beehive sounds to elephants in Kenya and found the sounds caused the elephants to leave the area and emit unique alarm calls to warn other elephants. After discussions with local farmers, King and her team placed hanging beehives around the crops of African farmers who might otherwise be in dangerous conflict with crop-raiding elephants. Followup studies confirmed the value of this approach (King et al., 2011, 2017, 2018). This team included scientific professionals and highly motivated community members who were knowledgeable about local conditions and behaviors necessary for the project's success.

The next two sections of this entry explore domains that have drawn particular interest from creative social changemakers: food and the arts.

Creativity and Social Transformation: Food

Food, besides keeping us alive, is the focus of culture, tradition, and family life. Currently it is also a focus of innovations that address social and environmental problems. Hunger has been addressed by new methods of communication and distribution. The serious harms caused by industrial agriculture and the cruelty of factory farming of animals have reached mainstream discourse, and markets for wholesome, organic, meatless, and local foods have increased, as have protests against the excessive political power of agrichemical corporations.

Beyond shareholder activism and personal purchasing power, some people use food to make a statement. Sean Sherman, Oglala Lakota chef and author of *The Sioux Chef's Indigenous Kitchen*, wrote that he does not make or encourage fry bread, often thought to be Native Americans' signature dish. To him, fry bread is a painful reminder of the injustices of colonialism.

I'm often asked why we don't have fry bread on the menu or offer a recipe for fry bread in this book. [Fry bread] originated nearly 150 years ago when the U.S. government forced our ancestors from the homelands they farmed, foraged, and hunted, and the waters they fished. They lost control of their food and were made to rely on government-issued commodities—canned meat, white flour, sugar, and lard—all lacking nutritive value. Controlling food is a means of controlling power.

Quoted in Wilson (2018, p. 3).

Food Supports Social Change

Another chef collected essays and recipes by and for activists in *Feed the Resistance: Recipes for Getting Involved*, which offers support for small groups as they gather around the table to plan their campaigns or prepare to feed large groups. Wrote one contributor, "We have plenty of work to do, and we intend to be well fed while doing it" (Zigas, 2017, p. 38). Wrote another:

Our multiracial movement building needs to be fueled by reconciliation and atonement. Food spaces and food people are unique champions to create room for, and facilitate, this healing. Unpacking this racial trauma is best served over warming bowls of peppery oxtail stew or silky dhansak. ... and white people will have to examine themselves, and with each other first; Creating anti-racist food spaces to dismantle white supremacy and patriarchy is a nourishing, worthwhile endeavor.

Simley (2017, p.80)

Slow Food USA, part of the international grassroots movement Slow Food, opposing all that fast food represents, encourages local, seasonal, and sustainable food. Furthermore, it promotes school gardens, chefs' alliances, sensible policy, and biodiversity.

Food Production

Huge machines are no longer universally seen as god's gift to agriculture. Besides the embedded energy and materials used to manufacture them, they use fossil fuels and stir up soil which is blown away and lost. But small robots bring new promise to machine-assisted agriculture. *Precision farming* (PF) is an approach in which planting, watering, tilling, and harvesting are guided by smart machines that give detailed information about each portion of the field, thus minimizing waste of seeds, water, and fertilizer and maximizing the harvest of ripe crops.

PF has the potential to increase productivity significantly, as well as reducing environmental impact the time is now right for these developments, as most of the necessary, enabling technologies such as GPS, GIS, machine vision, advanced sensors, pattern recognition techniques and autonomous vehicle technology already exist. Moreover, preliminary results suggest that robotic PF can be cost-effective.

Bogue (2013, p. 9)

The Rosphere is a ball-shaped autonomous robot compared by the researchers to the familiar pet toy Hamster ball. Rosphere is equipped with advanced electronics such as magnetometer, humidity and temperature sensors, GPS, tilt correction, and an inertial measurement unit. Having tested it on various surfaces and in cropland, the researchers concluded, "The performed tests have validated ROSPHERE's capability to move along wide crop rows while obtaining and geo-referring environmental data." Further improvements will allow Rosphere to be used on a broader variety of crops (Hernandez; Barrientos, del Cerro, Barrientos, and Sanz, 2013, p. 65).

Food and Culture

The diversity of food cultures offers a window into learning about the world. To encourage multicultural awareness among schoolchildren in California, the organization "Cooking Round the World" holds week-long summer camps and after-school classes, each focusing on a different country.

Each camp day we cook and eat 4 to 8 recipes, read a folktale, play an international/national game, observe a cooking demonstration, and learn to think critically about the foods we just cooked. In the afternoon we see a slide presentation, play a trivia game, have outside recess time, ...or bake desserts. Most weeks the focus is exploring cultures and food from around the world [showcasing] interesting cultural tidbits about the country's culture like marriage customs, family, education, toys and games, street art, how climate influences food, and fashion.

<http://cookingroundtheworld.com/camps.html>.

Indigenous peoples around the world have their own foods and traditions, which are threatened by globalization and which have attracted government and academic support. Kuhnlein (2009) noted that among 12 indigenous food cultures studied, there was a wide range in percent of traditional foods comprising their dietary intake, concluding, "A forward-looking approach is needed in all sectors to address Indigenous Peoples' food security, and for building attention on the rights of Indigenous Peoples to maintain their cultures, environments and preferred food systems" (p. 7). In Canada, The Center for Indigenous Peoples' Nutrition and Environment engages in research and participates in practical programs that honor connection to the land and the nutritional values of traditional foods.

Food Waste

One of the most unfortunate aspects of the distributed economy is the waste of food, the literal staff of life. It has been claimed for years that the world's farmers, fishers, and ranchers produce enough food to satisfy everyone on earth, but several factors prevent this optimal outcome.

- Losses during production, transportation, processing, and distribution
- Waste at destination, including rejection of slightly imperfect fresh foods
- Ill will, as when actors in distressed areas siphon off relief supplies or prevent them from reaching the intended population
- Economic opposition from large actors that obstruct innovation
- Inertia and investment in "things as they are."

Creative solutions reduce food waste. In the United States, the revived practice of growing one's own food has gained momentum. Community gardens, balcony containers, fruit and nut trees, and back yard plots are producing apples, lettuce, onions, beans, tomatoes, and more. For urban dwellers who are several generations removed from the land, planting, tending, and harvesting comprise a form of personal creativity – and an investment of time and energy that can reduce waste and the use of harmful chemicals.

High-tech inventions tackle waste: apps connect wholesalers or restaurants that have surplus to food pantries; online and delivery services distribute visually imperfect (but perfectly edible) produce that would otherwise be discarded by supermarkets; and other ingenious methods, such as a safe and edible coating for fresh produce that doubles its shelf life.

New Food Sources

Broadening our definition of what constitutes food can solve two problems at once, if we add invasive species to our menus. For instance, lionfish (*pterois volitans*) have colonized millions of square kilometers of the western Atlantic and Caribbean, outcompeting native fish and threatening them with extinction. Albins and Hixon (2013) predicted dire consequences and proposed mitigating strategies (removing them, encouraging potential natural enemies in marine reserves).

The ongoing spread of invasive lionfish throughout the greater Caribbean region will eventually be controlled either by starvation of lionfish, which would be the most extreme ending of the worst case scenario, or by native species (competitors, predators, parasites, and/or pathogens) finally providing biotic resistance to the invasion. Only time will tell whether local and regional control efforts, or simply nature running its course, will limit the potentially disastrous invasion of Atlantic and Caribbean coral reefs by Pacific lionfish. (p. 1156).

Note that the proposed solutions are expensive, bureaucratic in nature, or outside human control. But a simple solution for lionfish exists: Eating them. In fact, the market for lionfish is already established. Huth et al. (2016) also found that consumers would be willing to pay extra once they learned that lionfish were harming the local marine environment, and even more when they learned that the lionfish were threatening local commercial fish species with extinction. However, the practice of eating invasives (sometimes called "invasivorism" Snyder, 2017) must be undertaken carefully to avoid serious unintended consequences.

The Arts and Social Transformation

The arts can have direct social impact. Harriet Beecher Stowe's condemnation of slavery (*Uncle Tom's Cabin*, 1852) intensified anti-slavery sentiment and Upton Sinclair's *The Jungle* (1906) is remembered for jump-starting governmental regulation of meat packing, although that industry was only a small part of the author's denunciation of injustices in American society. *One Day in the Life of Ivan Denisovich*, Alexander Solzhenitsyn's 1962 realistic novel about Soviet prison life, launched the author's platform in the West, from which he exposed the failings of communism (and critiqued the West), donating royalties of his works and part of his Nobel Prize money to an aid fund for former Soviet prisoners and their families.

Movies (stories or documentaries) can reach vast numbers of people quickly on causes as diverse as health care, racial injustice, and the abuse of animals. Television has helped loosen prejudices and strengthen the confidence of women and minorities; for instance, the series *Roots* in the 1970s, dramatizing the abominable truth about slavery, was watched by millions, although recent events have revealed the deplorable continuance of racism and sexism in America.

Vaclav Havel, the often-jailed dissident playwright, was so respected in his country (Czechoslovakia, later the Czech Republic) that after communism fell, he was elected president and served for fourteen years. Picasso's painting *Guernica* and Goya's *The Third of*

May 1808 are among the most powerful indictments of war ever committed to canvas. Other creative forces for social transformation are theater, mime, movies, poetry, comedy, street murals, and protest songs.

Some people use the arts themselves as vehicles for social change. El Sistema is a program that began in Venezuela to teach less advantaged children to play classical music, offering alternatives to lives of drugs and crime. El Sistema has spread internationally and enrolls hundreds of thousands of children, yet is not without controversy. (One could say the same about many idealistic movements).

Theater of the Oppressed, originating in Brazil, is a collective art form purposefully devoted to social change, and uses inventive forms such as interactions with audience members to bring a social problem to life; real-life dialogues between citizens and legislators to dramatize a law's consequences; allowing spectators to interrupt a play and dramatize a more successful ending; re-enacting an oppressive incident, only with a more assertive protagonist resisting instead of acquiescing.

Professionally produced television episodes can address social problems. For instance, in South Africa, modes of financial exploitation were exposed in a soap opera television show teaching viewers to avoid loan sharks. Theater programs in prisons, such as *Shakespeare Behind Bars* and *Shakespeare for Social Justice*, promote literacy, communication skills, constructive group participation, self-esteem, and conflict resolution.

The boundary between art and social criticism has been blurred by the British provocateur Banksy, who uses graffiti and pranks to protest consumerism, war, greed, class, fascism, and a host of other traits of the modern world. Ironically, this anonymous person has become famous, and works of the artist who stays outside the art economy have become high-priced; to redouble the irony, Banksy sold one work for a million pounds, and then, as planned, it self-destructed.

However, creativity can also be used to intentionally cause harm. Terrorists invent ways to sneak bombs onto airplanes. Nazis created logistical and industrial systems for annihilating whole populations; they also used music (played by eminent orchestras led by top conductors) to whip up the crowds. Such creativity has been called "malignant" by Salio (2017), "malevolent" by Cropley et al. (2008), and the "dark side" by Cropley et al. (2010). Malevolent creativity was at work among German musicians who supported the advance of Nazism through militant songs, parades, and public concerts that celebrated their victories in the battlefield. Nazi leaders embraced the arts.

Culture was of the utmost personal importance to the Nazi leaders, many of whom were themselves failed artists – Hitler a painter and architect *manqué* as well as a passionate Wagnerian, Goebbels a would-be novelist and playwright, Goring a gluttonous art collector, Rosenberg a trained architect, von Schirach an aspiring poet. They raised culture to a central position in their so-called 'New Order' and used the arts as a means of gaining legitimacy (Spotts, 2008, p. 3).

Some of these musicians did not apparently pay a price for their collaboration with Nazis. Collaborationist conductors who continued to have careers at the highest international level after the war include Herbert von Karajan, Wilhelm Furtwangler, Karl Bohm, and Hans Knappertsbusch.

In our own day, resurgent neo-Nazis in many countries can call on the talents of web developers, writers, and photographers to promote racism, misogyny, anti-semitism, and hatred. One such group regrettably calls itself the Creativity Movement, claiming that white people are inherently superior and creative. As Salio wrote (2017, p. 30), "It is possible to identify a benign creativity, one directed at the nonviolent transformation of conflict, but also a malignant creativity implemented by those who do not even remotely intend to give up their power and privileges."

Returning to artistic creativity that expresses pro-social values, we can find photography to help war veterans heal; musical instruments being made from trash; songwriting to help the homeless and to help jailed mothers bond with their children; and bringing artists and scientists together to foster support for endangered species. These examples manifest the associative theory of creativity (Russ and Dillon, 2011, p. 66), which holds that "creative ideas occur when disparate elements come together to form a new idea or solution to a problem."

Who Is Doing It?

As Richards (2011) asserted, creativity is not limited to the eminent or the professionally trained. It is a faculty that can be employed by most people. This is particularly true in social change, where, as we have seen, useful inventions and ideas have come from children, farmers, teachers, activists, and others who were not professionally trained in the field in which they innovate (perhaps lack of training actually made their fresh insights possible). After developing their ideas, they may gather resources from other individuals, groups, or businesses in order to bring them to the target places and populations.

Children. Kindergarteners and first- and second-graders from the Homestead School in New York have since 1991 made and sold handicrafts, raising over \$128,000 to purchase and protect over 1,000 acres of rainforest in Central and South America. Twelve-year-old Haile Thomas started a program to teach underserved children about healthy nutrition. Nine-year-old Mason Perez's science fair project helped his community save tens of thousands of gallons of water. Many other children have devised and executed solutions to real-world problems. Some of these ideas were conceived independently by children, while others were submitted to projects suggested by teachers or organizations.

Teens and Young Adults. Malala Yousafzai won a Nobel Peace Prize at age 17 for advocating fearlessly, at the risk of her life, for the rights of girls to an education. Kenyan youth Richard Turere, 13, created a lighting system from castoff elements that protected his family's livestock from lions prowling at night. Eighteen-year-old Dutch student Boyan Slat designed a collection system for removing plastic waste from the Pacific Ocean, attracted millions of dollars of support, and launched it in 2018.

Organizations. There are also organizations whose mission is to support other innovators, such as Ashoka: Innovators for the Public, a charity dedicated to finding and fostering other social entrepreneurs worldwide. The Foundation Center is a nonprofit dedicated to helping other nonprofits find and secure funding. Slow Food, mentioned earlier, locates and funds inventive food entrepreneurs, emphasizing the preservation of biodiversity.

Benefit corporations (B corps). Over two thousand companies worldwide, especially those dealing with food, sustainable energy, and technology, voluntarily commit to acting with sustainable and socially positive values. The B Corp Declaration of Interdependence states:

We envision a global economy that uses business as a force for good. This economy is composed of a new type of corporation – the B Corporation – which is purpose-driven and creates benefit for all stakeholders, not just shareholders. As B Corporations and leaders of this emerging economy, we believe:

- That we must be the change we seek in the world.
- That all business ought to be conducted as if people and place mattered.
- That, through their products, practices, and profits, businesses should aspire to do no harm and benefit all.
- To do so requires that we act with the understanding that we are dependent upon another and thus responsible for each other and future generations.

In practice, B corps, which exist in 60 countries around the world, members take responsibility for their supply chains, workers' rights, carbon footprint, waste prevention, healthy environment, and racial justice. Apart from their very existence as a healthier form of doing business, B-corps make social and environmental commitments such as hiring the formerly incarcerated, reducing waste to nearly zero, moving people from welfare to work, and making carbon-neutral products.

Who Is Supporting It?

Agents of social change have received financial support from a variety of sources: philanthropists, charitable funds, government bodies, venture capitalists, industry-funded competitions, and from that well-known social invention, crowd-funding.

Unrestricted awards. Perhaps the best-known and most unusual one is the MacArthur Fellows Program, also called the MacArthur Fellowship, or "Genius Grant," a prize of \$625,000 (paid over five years) awarded annually to about 20 individuals. Recipients, who may work in any field, have no idea they are being considered for the prize. They have shown "extraordinary originality and dedication in their creative pursuits and a marked capacity for self-direction" and are citizens or residents of the United States. The unusual feature – itself creative – is that, according to the Foundation's website, "The fellowship is not a reward for past accomplishment, but rather an investment in a person's originality, insight, and potential." Their creative fields have included poetry, physics, history of religion, archeology, theater, and many others. For social change, MacArthur grants have been given to community organizers, activists, and social entrepreneurs.

Environmental awards. The Goldman Environmental Prize, sometimes called the "Green Nobel," has been awarded since 1990 to 6 grassroots environmental activists annually, one each from Africa, Asia, Europe, Islands and Island Nations, North America, and South and Central America. Each prize includes international recognition and \$175,000. For example, Francia Marquez organized women in Colombia to halt environmentally destructive illegal gold mining in their ancestral lands.

The United Nations Environmental Programme has honored individuals and organizations for their achievements in the Global 500 Roll of Honour and the Champions of the Earth. The meat alternative producers Beyond Meat and Impossible Foods won the award for their successes in successfully creating and marketing protein foods that do far less damage to environmental and human health than foods made from animals.

Foundations. The Foundation Center lists 140,000 U.S. charitable foundations. That's far too many for even a cursory survey here, but to highlight a few of the largest ones: Bloomberg Philanthropies supports projects as diverse as reducing drowning among children in Bangladesh, bypassing Washington and instead harnessing the power of mayors, and using technology to monitor the success of anti-smoking campaigns. The Bill and Melinda Gates Foundation, focusing on global health, poverty, and education, has supported projects to improve sanitation (such as funding a competition to reinvent the toilet), digital banking systems in poor countries to empower the very poor, and tackling neglected infectious diseases. Meanwhile, conservationists in the field work, often in isolation, to protect endangered species, and non-profits like Wildlife Conservation Network fund them. The Robert Wood Johnson Foundation encourages innovation by accepting "Pioneering Ideas Brief Proposals that can help us anticipate the future and meet our nation's health challenges in unexpected ways" – for example, by encouraging cities to consider mental and physical health in their building and zoning plans.

Industry grants. Even very young innovators have opportunities to showcase their ideas and win funding and practical support. For the 3M Young Scientist Lab Challenge, American students in grades 5 through 8 are invited to submit a 1- to 2-min video describing a unique solution to an everyday problem for the chance to win \$25,000 and an exclusive 3M Mentorship. Past winners include Gitanjali Rao, who invented a quick and inexpensive way to test water for lead contamination; Maanasa Mendu, who used efficient and eco-friendly piezoelectricity materials to support wind power; and Hanna Herbst, whose device taps energy from ocean currents to store in a generator. Note that all three recent winners have been girls, two of them from minorities.

Government grants. The United States federal government offers grants through dozens of its departments and administrations. State and local authorities may also fund regional or local projects, such as a California parks department plan to save the

endangered murrelet, a small bird species. Inspired by a graduate student's idea, researchers added a tasteless, odorless vomit-inducing chemical onto decoy murrelet eggs. This effectively reduced predation by Steller's jays.

Indigenous or indigenous-inspired organizations. The Redhawk Native American Arts Council, based in New York City, promotes traditional culture and contributions of Native Americans with heritage celebrations, song, dance, arts and crafts. Other Native organizations share these and other goals, and are supported by the work of Native Americans in Philanthropy.

Incubators, as they are called in the business world, are organizations such as Ashoka, mentioned earlier, through which individuals or small organizations receive support in various forms for developing their ideas. Another is the Biomimicry Launchpad, which helps early-stage innovators gain inspiration from nature to solve problems. For instance, Nexloop.us (which won the \$100,000 Ray of Hope prize in 2017) is a water capture, storage, and distribution system, based on nature principles, for supporting urban agriculture. Multiplier.org serves as an established 501(c)3 nonprofit home for startup projects, allowing them to receive funding without having to set up their own tax-exempt status, complex legal certifications, and back-office staffs.

Investors, such as New World Capital, channel venture capital to sustainability projects such as clean energy, clean energy, and water reclamation. The credo of Obvious Ventures is, "The most valuable companies of our time will be the ones solving humanity's biggest problems." Honeycomb Portfolio invests in projects that tackle sustainability, overconsumption and waste, and health of women and children.

Crowd-funding. Websites like GoFundMe and Kickstarter are known for private requests; they also acquire funds for inventors and help nonprofits hold fundraisers, collectively channeling millions of dollars directly to innovators. Many such projects are commercial; some, however, are for the public good, such as the Human Rights Campaign. Some are both, such as helping a vegan caterer establish a restaurant that serves only socially responsible dishes and also donates to community non-profits.

South by Southwest is a high-profile ten-day conference for creative change-makers, with dozens of themes plus spinoff events and networking. The track Social and Global Impact includes topics such as citizen science, gender rights, violence prevention, preserving ecosystems and species, children's rights, and framing one's work in positive rather than negative terms.

To sum up, those who dream of solving the world's problems do not have to dream alone.

Conclusion

The creative processes used to develop the many social innovations mentioned here were not typically described. But using the creativity literature, we might speculate about them. The associative theory of creativity (Russ and Dillon, 2011) suggests the value of making uncommon combinations of elements. Einstein called this "combinatorial play" and it can lead to practical novelties. For instance, robotics inventors have made surgery more precise; horseback riding helps disabled children improve their balance; raising puppies that are later trained as guide dogs helps socialize prison inmates. Ping pong diplomacy – using an indoor sport to open doors between the United States and China – was the first step in improving relations between the two countries.

Agnoli et al. (2018) pointed out that (like Wallas's classic stage of incubation) mind wandering can enhance creativity. Jiang and Thagard (2014), looking specifically at social innovation, emphasized the cognitive processes of association, analogy, and problem-solving, but also accentuated the importance of emotions such as frustration and hope, and the luck of serendipity. More generally, children have had less time to internalize the constraints of their cultures, so may be more open to fresh perspectives. Adults can consciously look beyond their assumptions and customs, exploring alternative ways of life through travel or education. Whatever the creative path they use, people of all ages, nations, races, and classes are confronting our problems with ingenuity and hope.

Introduction

For several decades, creativity has attracted the attention of representatives of such sciences as psychology, including socio-psychology, sociology, philosophy, including aesthetics, pedagogy, cultural studies, economy, management, urban studies, regional studies, and, finally, bibliometrics. The sociology of creativity is interested in all the approaches above. For sociological research, not only empirical indices of creativity and not only the influence of creativity on the development of society, but also the concept of a creative society becomes important. This concept plays the role of a “cap” for empirical research.

In this entry, we first compare the different studies of creativity in the social sciences, then present the concept of a creative society, and finally analyze the possible indices of a creative society and their problems.

Studies of Creativity in the Social Sciences

Table 1 shows the areas and sub-areas of creativity studies in the social sciences. Since the social sciences differ from, say, the humanities, by adopting a more or less empirical approach, the table also includes the indicators of creativity. It seems that creativity is first and foremost a topic for the humanities and arts, but in this entry we will limit ourselves to creativity research that is interesting for a sociological approach. The humanistic (say, philosophical) approach is as important here as it complements the sociological one. For example, the very definition of creativity inevitably appeals to philosophy as a view from the outside. **Table 1** does not exhaust all possible approaches to creativity. For example, technological sciences also deal with creativity.

First of all, the phenomenon of creativity attracted the attention of psychologists. The empirical research into the psychology of creativity is since the 1950s. In the seventh decade of the last century, an empirical test of creativity was launched (Torrance, 1966). In addition, relatively long ago, psychologists also realized the negative aspects of creativity (Rank, 1989/1929). Negative aspects can be assessed as the limits that imply the ethics and ecology of creativity; therefore, they are extremely important for the concept of a creative society. Following the Torrance test, various indicators of creativity were proposed, including an imagination index. For example, tolerance for uncertainty, which usually accompanies creative initiatives in society, was analyzed (Kornilova and Kornilov, 2012).

Researchers analyzed different psychological aspects of creativity, which is primarily related to originality, as well as the relationship between creativity and certain behaviors or characteristics that are inseparable from the social environment. As a result of the interweaving of the psychological and sociological areas, in the case of creativity, different integrative indices are introduced (Reiter-Palmon et al., 2009), as well factors (Carroll et al., 2009) to measure creativity and its role in society, including SEKI (Chang et al., 2014), IPK (Carroll et al., 2009) and OKFTA (Kaufman et al., 2009).

As mentioned, a scientific approach to creativity does not do without a specific meta-science, i.e., an outside view that helps determine the phenomenon itself and its social role. It seems that any scientific discourse should begin with this philosophy. On the other hand, this also requires a certain framework, in our case, a sociological context. When defining creativity, researchers refer to etymology (Amabile, 1983; Runco, 2004), semantics and hermeneutics (Uggla, 2017). Beside this, we can speak also about the phenomenology of creativity. The structural approach to this extensive term also helps to understand the phenomenon (Simonton, 2012). Attempts to evaluate academic creativity by citing scientific publications (Hirsch, 2005) can also be attributed to approaches from the outside. In this case, we are talking about a bibliometric approach.

Social criticism, which usually refers to Karl Marx, primarily attempts to evaluate creative work, in which exploitative elements are not excluded. In this regard, the concept of a creative class (Florida, 2002) also does not avoid references to the Marxist division of society into classes according to professional characteristics. On the other hand, from the Marxist standpoint, one can analyze the creative potential of the working class, in whose hands is the creation of a new society.

Table 1 Scientific approaches to creativity (C).

<i>Scientific areas</i>	<i>Sub-aries</i>	<i>Creativity research indicators</i>	<i>References</i>
Psychology	Psychosomatic processes	Torrance test	Torrance, 1966

Sociology	Meta-science, definitions of creativity in academic writing	Hirsch Index (H-index)	Hirsch, 2005
	Meta-creativity	Negative aspects of creativity	Rank, 1989/1929
	Aesthetics	Creativity in art	Juzefovič, 2015
	Social theories	Creative environment	Baltrėnas et al., 2015
Pedagogy	Climate of creativity	Indices of a creative climate (environment); factors of correlation between climate and creativity	Baltrėnas et al., 2015
	Quantitative methods (surveys, calculations)	Mathematical models for calculating creativity	Carroll et al., 2009
Pedagogy	Pedagogical methods	Predictors of creativity	Juzefovič, 2015

Speaking of philosophy in a narrower sense, it can be noted that its aesthetics section deals with issues of creativity in art (Juzefovič, 2015). In this case, the social environment plays an important role (Baltrėnas et al., 2015). Creativity is also analyzed as a pedagogical factor (Juzefovič, 2015).

Research on economics and management analyzes the issues of innovative products on the market, cultural (creative) economy (Howkins, 2007), and intellectual capital related to creative capital (Florida, 2002).

Regional studies raise questions about the creative factors in the development of both cities, and insufficiently urbanized regions. In addition, urban studies are engaged in establishing sociocultural qualities, assessed by creative industries, cultural clusters and creative products in the city.

So, sociology faces issues of creativity at four levels: (1) relying on certain sociological theories, (2) analyzing the social environment of creativity, (3) applying qualitative sociological methods to the study of creativity and (4) searching of empirical indices of creativity.

The Concept of Creative Society

As can be seen from the above, the concept of a creative society has a solid basis. Creative industries suggest the creative class as a new social formation (Florida, 2002). It seems the creative class is the core of a creative society. The number, weight and activity of the creative class predetermines the role of creativity in society. Still, there are several problems here. First, the creative class is not a new formation. It can even be considered the criterion of any outstanding historical civilization. Secondly, it is unclear how to define the creative class. If we define the creative class too narrowly (say, only as a class of artists), its role in society will be insignificant. If we define it too broadly (including engineers, doctors, bankers and businessmen) in the manner of Florida (2002), it will lose his identity. Finally, the concept of a creative society presupposes the idea that every individual is creative enough. There is no reason to speak about a creative class in this case. Although the segregation of our society increases, the division of it into the classes is a kind of Post-Marxist discourse if everybody has equal possibilities within a democratic environment. As a result, the concept of creative society represents a neoliberal approach that is hardly compatible with a Post-Marxist division of society into the classes (including creative one) as the holders of social capital.

Additionally, the question arises about the relationship between the knowledge society and the creative society. It seems that creativity requires more and more knowledge and skills in an environment filled with technology and media. As a result, creativity occurs in a knowledge society where creativity is only an aspect of promoting knowledge. Still, creative relationships imply entirely different social ties that predetermine changes in both labor relations and lifestyle. In addition, the priorities of creativity predetermine political changes. Finally, the fact that creativity is inseparable from knowledge does not mean that the first is an aspect of the second, and not vice versa. So, the discourse of the knowledge society does not remove and does not subordinate the discourse of the creative society, since the latter emphasizes the corresponding trends in social development.

Another aspect of creative society—that it or a part of it, such as a class or an individual—is something outstanding. We encounter this aspect or phenomenon in several ways. First, we are talking about an outstanding artist in a narrow and about an outstanding creative worker in a broad sense. But this is a problematic issue. On the one hand, any artist or creative worker is a child

of his or her environment, who also plays a certain role in this process. On the other hand, an outstanding individual also implies a hermeneutic and communication gap, that is, a lack of understanding and ignoring of his (her) work; finally, outstanding individuals are undesirable in a media environment where ratings and mass audience are priorities. Secondly, we can talk about an outstanding community, including a class. For example, the creative class (if we recognize this) is outstanding both because of its creative achievements and due to its influence on society, although it is not the largest class. The problem here is that in a democratic society with its majority rule, a relatively small creative class can hardly influence political decisions. This suggests an unpleasant idea that a democratic and creative society do not agree. Some researchers (Florida, 2002) try to solve this problem by expanding the scope of the creative class, but this creates difficulties in identifying it.

As mentioned, we can talk about an outstanding creative society. In this case, we face another difficulty: if a society is understood as a social community encompassing individuals and communities, then is it outstanding in relation to what? A creative society can be outstanding unless in relation to a knowledge society or an industrial society, which imply a different theoretical approach and other priorities. However, in this case it does not indicate different societies, but the development of the same society, when certain aspects become irrelevant.

The creative society involves a creative lifestyle. The changed labor relations show it: freedom in choosing work schedules, long vacations, which are most often sacrificed for creative work, informal relations, when offices and institutions that administer creativity disappear, autonomy and responsibility in making both working and life decisions, inability to count working hours, on the other hand—hard work, short-term duties to the employer and consequently reduction in social guarantees. In other words, the creative worker balances between the desire to go beyond formal labor relations and the obligation to remain inside the labor market with some social protection. In general, the social life of a creative worker is varied in form. Still, in most cases we are not speaking about waiting for rare moments of inspiration, but about hard work and self-discipline. Finally, both the creative worker and the creative society are characterized by the principle of ignorance. It manifests itself not so much in ignorance about the future impact or success of the work, but also in ignorance of what will affect the emergence of the work.

The question arises whether there is a limit to creativity. Thus, it is a question of creative ecology and creative ethics. Each work of art, more or less individual, is limited by its social environment, which it puts forward or forgets. Creative ecology primarily appeals to the purification of consciousness from creative pollution (Howkins, 2009). The creative ecology is a certain strategy for forming the content of consciousness. This is necessary both for individual creativity and for the renewal of society. Ecology is a narrow transition between social mobility and social stagnation. In general, for ecology, individual creativity in the conditions of social engineering and the production of mass happiness is important. The expansion of the social horizon for individual creativity, which always arises in a certain social environment, is also connected with ecology.

Creative ethics also appeal to the limits of creativity, although it interprets stagnation as unethical behavior in relation to the creative society. A colorful creative society without the same rules implies different behavior. Although Immanuel Kant associated ethics with reason and rationality, creative ethics encounters irrational moments when the behavior of an individual is predetermined by his creative sensations and stimuli. We can talk about two sections of creative ethics: the content of the first is the creative aspect of ethics, the second is the ethical issue of creativity. On the other hand, one can speak of three ethics by social dimension: an individual, a communal, and a social. The first covers the aspirations of the creative worker, the second appeals to the professional activity, the third has in mind the universal maxims. A creative worker is an agent of all these ethics and their sections. Moreover, certain tensions or even contradictions between these ethics become creative stimuli. Creative ethics appeal to the unusual behavior toward these contradictory ethics, although it seems unethical from other ethical perspectives.

Empirical Research of Creative Society

The difficulties specific for empirical studies of creativity stem from the non-empirical nature of creativity. From a sociological point of view, studies of a creative society need empirical indices of creativity. Therefore, Florida puts forward certain indices of creativity: Bohemian, High Tech, Innovation, Gay, Talent, Melting Pot, and their integrative indices (see Table 2). It seems that it remains to count them, to evaluate national, professional and religious communities, as well as to form policies that encourage creativity. But here the problems are just beginning. With respect to each of these empirical indices, methodological difficulties arise that cause doubts in the empirical approach to creativity in general: either these empirical indices do not sufficiently substantiate creativity, or they cannot be counted empirically.

For example, in the case of a Bohemian Index (that refers to creative workers in the narrow sense or artists) it is not clear who makes up this group. Are performers, (computer) designers, inventors, educators, scientists, DJs, graphitists considered as artists? Here a problem arises, as in the case of the creative class. Wanting to give a great influence to this concentrate of creative society, researchers tend to expand its boundaries, but then there is a threat to its identity. In addition, it is difficult to separate the artist from the manager and technologist in a post-modern and post-industrial society. Finally, it is unclear how much the artist must be outstanding in order to be counted among this layer. So, the volume of the Bohemian Index depends on the question arising from the policy in the field of art and creativity: how much does a consumer community need an artist with his disinterested vision?

When we try to determine the High Tech Index, first of all there is the difficulty of separating high technologies from “low” technologies. In addition, high technologies are becoming a means of leveling creative activities instead of encouraging creativity. It seems that the Innovation index, which is determined by the number of patents, speaks not so much of creativity as of a lower

Table 2 Indices of creativity R. Florida.

No.	Index	Integrative	Indices
1.	Bohemian		
2.	Melting pot	Minor integrative	
3.	Gay	(Diversity) index	
4.	High tech	–	Major integrative index
5.	Innovation	–	
6.	Talent	–	

or higher social barrier in this regard. Moreover, the number of patents does not show the influence of inventions on social development after their implementation. Finally, the growth in the number of patents shows trends not so much creativity as consumption.

It is impossible to measure the Gay Index not only because statistics on this “sensitive” issue is hardly possible, and the phenomenon of bisexuality indicates that the boundaries of homosexuality are unclear. Difficulties result from the fact that being gay is primarily a cultural, not a physical (sexual) category. The Talent index, which expresses the percentage of high school graduates, indicates not as much the talent (and thus creativity) of society as the attractiveness of higher education. A high Talent Index also shows a devaluation of higher education, i.e. an orientation toward the average level, which is the opposite of creativity. The Melting Pot Index, which expresses the percentage of immigrants, does not show the diversity (which implies creativity) of society, but the probable closeness of sub-societies. In addition, the idea of a pot leveling cultural margins does not express creativity, which appeals to the cooperation of the cultural center and cultural margins. The empiricity of integral indices (Minor and Major), which at different scales cover the mentioned indices, is questionable not only because their components are problematic and difficult to measure, and not only because they cover only part of the possible creativity indices, but also because that they appeal to what is behind empiricism, i.e., to historical consciousness, worldview and transmission of tradition.

In addition to those mentioned above, alternative creativity indices can be advanced. For example, the Emigration Index, which in some sense is the opposite of the Melting Pot Index, as it appeals to emigrants, and not to immigrants. Still, it expresses the freedom and tolerance of society: the least of all emigrants are from a totalitarian society, which can hardly be called creative. The Suicide Index seems to express the unhappy state of society, which is not consistent with creativity. Still, he shows the freedom of “exit” in a creative society. The indices of economic growth, sociability and urbanization also express creativity, although not in a straightforward way. Economic growth implies more intensive creative activities. Sociability (including social networks) involves the exchange of creative ideas; a large number of cities and their sufficient size presuppose additional creative possibilities.

Conclusion

The sociology of creativity is interested in different inter-disciplinary approaches including socio-psychology, philosophy of creativity, cultural studies, urban studies, bibliometrics etc. For sociological research, not only empirical indices of creativity and not only the influence of creativity on the development of society, but also the concept of a creative society becomes important. Sociology faces issues of creativity at four levels: (1) relying on certain sociological theories, (2) analyzing the social environment of creativity, (3) applying qualitative sociological methods to the study of creativity and (4) searching of empirical indices of creativity. Additionally, the concept of a creative society has a solid basis. The creative society involves also a creative lifestyle. The question of creative society arises whether there is a limit to creativity. Thus, it is a question of creative ecology and creative ethics. The difficulties specific for empirical studies of creativity stem from the non-empirical nature of creativity. However, from a sociological point of view, studies of a creative society need empirical indices of creativity.

Creativity in Sports and Performing Arts

The sport environment is more challenging, unpredictable, and distracting than ever before. Athletes aspiring to the top level must reinvent themselves on a regular basis to keep an edge on their competitors. Whether it is to create novel and irregular movement patterns, or perform versatile tactical decisions during game play, creativity has become a crucial asset for the achievement of excellence in sport (Santos et al., 2016). Consequently, this entry presents an overview of the scientific literature related to creativity in the motor domain. It aims at describing terms, processes, measurement tools and resources to draw an accurate portrait of the state of the knowledge about creativity in sport and performing arts.

Motor Creativity

Bodily-kinesthetic or motoric creativity can be expressed differently depending on whether an individual is faced with the conditions characterizing artistic or acrobatic motor activities or with the conditions depicting team games. On one hand, the combination of perceptions into new motor patterns that is either a solution to a pre-established problem or the expression of an idea or an emotion by the means of the human body can be defined as *motor creativity* (Bournelli et al., 2009). Multiple sport breakthroughs resulted from sculpting new movement patterns. For instance, in 1968 Mexico Olympics, Dick Fosbury won the gold medal in high jump and set a new world record using an innovative, radically new approach. Instead of jumping over the bar face first, Fosbury decided to turn as he left the ground such that his back was to the bar. The Fosbury “flop” marked a revolution for the sport of high jumping. In 1970, gymnastics also progressed tremendously, largely because of the immense creative talent of Mitsuo Tsukahara. To compensate for an inability to locate himself in the air, the Japanese gymnast created the “Tsukahara vault” and thereby transformed the direction of vaulting by adding twisting to rotation. Although not competing for medals when they get on stage, performing artists such as dancers and circus performers are also pushing movement innovation to blow the mind of spectators show after show.

Tactical Creativity

Creativity in sport can also be expressed by athletes through unpredictable decision making in interactive, open-skill sports. Unexpected tactical solutions to situations that appear unresolvable to others can take the form of a surprising no look pass, a dribbling move to outsmart a defender, or a novel running routes to get a teammate open for a pass (Kempe and Memmert, 2018). The capacity to take varied, rare, and flexible decisions during game play is referred to as *tactical creativity* and is nowadays considered as a decisive factor for team sport success (Memmert, 2015). For instance, the examination of the eight actions preceding all goals in the Football FIFA World Cup 2010 and 2014, as well as the Football UEFA Euro 2016 revealed that teams exhibiting the highest level of tactical creativity are those that advanced to the later rounds of the tournament (Kempe and Memmert, 2018).

Figure 1 Cognitive processes underlying optimal decision making in team sport (Memmert, 2015a).

Psychological and Historical Creativity

Although the examples provided so far are showcasing outstanding demonstrations of creativity in the motor domain, developmental expression of creativity is not to be ignored. Similar to the everyday – eminent creative behaviors continuum, motoric creativity is classified in two main categories: *psychological creativity* and *historical creativity*. The former entails the discovery of a functional motor behavior that was not a part of the initial performers “repertoire.” In other words, creativity can happen without regard to whether such solutions already exist in the socio-cultural environment of the performer (Hristovski et al., 2011). The latter represents unique, socially recognized movement innovation, as exemplified by Fosbury and Tsukahara. To better capture the mechanism underlying creativity in the realm of motor performance, the following section provide an overview of a cognitive and an ecological dynamics framework.

A Cognitive Framework

According to the cognitive conceptualization of creativity, ideas are first generated in the mind, and then transformed into motor behaviors. Hence, divergent thinking – the cognitive process of generating many alternative ideas – may be a prerequisite for being creative in movement. Empirical evidence support that assumptions by highlighting overlaps in the processes conducive to the generation of creative thoughts and movements (e.g., Scibinetti et al., 2011).

Divergent thinking (DT) is also involved in the generation of creative tactical solutions during game play (Memmert, 2015). As illustrated in Fig. 1, DT is one of many cognitive processes leading to optimal decision making which refers to the process of making a choice from various options with the potential of having crucial consequences. Specifically, an athlete first anticipates and perceives a sport situation based on past experiences. The player then attends to visual cues in the environment and directs his/her attention to the most relevant ones. With these visual cues and knowledge in mind, divergent thinking allows the athlete to generate a range of ideas. Convergent thinking subsequently guides the athlete towards the best possible solution to be executed. Finally, if changes occur in the environment, alternative solution(s) can be explored and executed (Memmert, 2015).

Since DT is considered a good predictor of creative potential, sport researchers used general DT tasks to examine the link between creativity and motor expertise. For instance, Richard et al. (2017) showed that world class and Olympic athletes exhibited significantly higher DT score than non-expert athletes. The difference was particularly clear in ideational flexibility. Professional dancers, on the other hand, produce a larger number of ideas (fluency) than novice dancers (Fink et al., 2009). These results extend the report of a trend with skilled handball players outperforming non-skilled players on DT tasks (Memmert, 2015). Despite this evidence, the degree to which this high level cognitive skill is required for generating creative motor responses is still under debate. Creativity being a domain-specific skill, it is not certain that creative thinking will transfer into specific creative motor behaviors.

An Ecological Dynamics Framework

Orth et al. (2017) recently challenged the traditional cognitive view by using an ecological dynamics perspective. Rather than considering action as a mere expression of the creative cognitive system, they argued that creative motor solutions emerge through perception-action coupling within the environmental constraints. The structure of the physical environment, biomechanics of the body, perceptual information, and task demands determine the boundaries within which the motor system can act influencing the repertoire of actions available (Seifert et al., 2016). Moving creatively thus reflects an individual’s capacity to adapt in a unique and original way (Hristovski et al., 2011).

Both movement stability and flexibility are essential components of adaptability when individuals are encountering constraints. Behavioral adaptation thus comprises both adapted and adaptive behaviors. Adapted behaviors denote behavioral stability against perturbations whereas adaptive behaviors solicited behavioral flexibility to generate functional solutions under interacting performance constraints. Flexibility is thus an indicator of adaptation because it facilitates changes in behavioral patterns while preserving functionality. Also called degeneracy, this flexible motor adaptation is what leads to creativity and innovation (Seifert et al., 2016).

Measurement of Motor and Tactical Creativity

Whether we adopt a cognitive or a behavioral view to explain how creative movements and tactical decisions are produced, both frameworks support the idea that creativity can be nurtured in athletes and performers (Santos et al., 2016). Therefore, assessment tools were designed to directly tackle the improvement of creative motor behaviors.

The Motor Creativity Test (MCT), Thinking Creatively in Action and Movement (TCAM), the Bertsch task, and the Divergent Movement Ability test (DMA) are instruments that aimed at differentiating children ability to produce creative kinaesthetic responses to problem of a motor nature. To investigate motor creativity in adult population, an agility ladder task has recently been developed (Moraru et al., 2016). These assessment tasks encourage participants to solve motor problems in as many ways as possible by producing original movements. Methods using sport-specific movement video analysis also exist. These look at the transformation of traditional movement technique into more innovative ones (Torrents et al., 2015).

To assess the creative decision-making process, two methods are most frequently used: *video test* and *game test* situations (Mehmert, 2015). *Video test* presents highly standardized scenarios that require athletes to imagine themselves as the acting player in clips showing a sport-specific offensive play. When an offensive decision must be made, the image is frozen, and the athlete must name as many solutions as possible in relation to what he/she sees. Presenting a higher ecological validity, *game test* situations are ball games involving a single tactical component at a time, with fixed numbers of players as well as defined rules and environmental conditions. Creativity ratings of a chain of actions (e.g., dribbling, crossing, passing, or ball transport) leading to a desired sport outcome (e.g., scoring a goal) during official games is the most ecological method to assess tactical creativity (Kempe and Mehmert, 2018).

The behaviors exhibited during the various creativity tasks are usually video recorded and rated by several independent sport experts or trained assessors. As with divergent thinking tests, *fluidity*, *flexibility*, and *originality*, are among the criteria frequently used to evaluate participant's motor responses (Mehmert, 2015). *Fluency* denotes the ability to produce many movements or strategies; *flexibility* refers to the ability to generate motor solutions that pertains to different categories; and *originality* represents the capacity to generate seldom motor responses contrasted with a sample dependent norm.

Resources Supporting Motor and Tactical Creativity

The sport-specific creativity instruments presented in the previous section are frequently used to elucidate under which conditions creative motor behaviors blossom. Cognitive, affective, and environmental resources interact together to support the emergence of creative behaviors. Therefore, the next section highlights how those specific resources influence motor and tactical creativity.

Cognitive Resources

Anchored in a cognitive perspective, sport expertise is linked to superior executive functions. This umbrella term overarching cognitive processes such as working memory, attention, and inhibitory control is necessary for the regulation of thoughts and behaviors. Creativity is also associated with higher-level cognitive functions. Hence, investigating the potential linkage between executive functions and creativity in the motor domain is a valid method for testing this claim.

For example, working memory maintains new information in a heightened state of availability. Consequently, larger working memory capacity (WMC) is thought to allow individuals to override the tendency to stick to more traditional readily available solutions. In the motor domain, taxing working memory was not predictive of the diversity of motor solutions nor the originality of responses in both adult (Moraru et al., 2016) and children (Scibinetti et al., 2011) populations. Studying the impact of domain-general WMC on experienced soccer players' tactical creativity revealed similar results (Furley and Mehmert, 2015). Because a -potential solution is strongly activated by an expert's prior knowledge, high level WMC may fix the individual attention on the well-known solution, preventing more novel ideas from being explored.

Attentional strategies may thus facilitate creativity. Specifically, attending to a broad range of stimuli (i.e., broad focus) enables the access to distant and diverse ideas which, when connected together, lead to increased flexibility and originality. This holds true in sport. For instance, evidence highlighted the positive influence of a 6 months attention-broadening training program on tactical creativity in children. In this vein, evidence showed that advanced handball players who noticed the open player in an inattentional blindness paradigm video task produced significantly more original and flexible tactical solutions than those who missed it (Mehmert, 2015). Using eye-movement registration system to compare the visual search strategies of most-creative and least-creative soccer players, the positive role of broader attention was confirmed. The most-creative players detect a greater number of well-positioned teammates and they noticed them faster than their least-creative counterparts (Roca et al., 2018).

A slightly different trend was observed when examining the impact of breadth of attention on motor creativity. After priming either broad or narrow attention, Moraru et al. (2016) found that motor flexibility - but not originality - is affected by broad attention. Facing a motor task, a broad focus may trigger the performance of different modes of locomotion. Yet, because the task requires motor capacity, low skilled individuals may be unable to express in movement the responses of their original thinking process. In other words, broadening attention may only impact motor originality in population exhibiting greater physical literacy - the ability to use cognitive processes to move with confidence in a range of environments.

Likewise, original movement production is influenced by cognitive inhibition. Scibinetti et al. (2011) showed that while high level of inhibitory ability is predictive of original movement generation, originality in creative thinking is associated to low levels

of inhibition. Lower inhibitory ability is known to allow the emergence of loosely connected associations facilitating the production of original ideas. However, the planning of more complex movement output may require higher inhibition abilities to suppress the production of more common routines and let alternative movement ideas come to mind at least in a children population.

Not considered as an executive function, domain-specific knowledge is nevertheless a mandatory cognitive resource to innovate and push a field further. Although this is well accepted, the preferable method to acquire this knowledge remains an active debate in the motor domain. The next section shed light on this debate by exposing the optimal environmental learning and training conditions to foster creativity in the motor domain.

Environmental Resources

To master motor skills, deliberate practice is known to be an efficient method. Broadly defined as the engagement in highly structured training activities, extensive amount of *deliberate practice* hours is associated with greater level of tactical creativity in athletes of various team ball sports (Memmert, 2015). Yet, physical literacy also benefit from diversification and freedom (Santos et al., 2016). Because it promotes a broader spectrum of experiences and outcomes, diversification of motor activities during the first phases of athletic development favor the enhancement of creativity (Santos et al., 2016). Accordingly, accumulated hours of *deliberate play* – an informal involvement in sport games designed to maximize enjoyment – is linked to increased tactical creativity in young athletes (Memmert, 2015). This in turn suggests that creativity may not only benefit structured expert knowledge, but also need to be supported by modifiable cognitive representations.

To promote the acquisition of innovative and functional movement patterns, Hristovski et al. (2011) suggested a model of neurobiological creativity grounded in an ecological dynamics perspective. Because performers neurobiological system is complex, it provides a platform for multi-stability (i.e., the capacity to possess many co-existent patterns forming propensities) which is a prerequisite for metastability to happen. When the environment is designed to trigger meta-stable regions of the performance landscape, performers' system momentarily dwells between stability and instability. To efficiently deal with the chaos and regain stability, they must generate co-adaptation strategies to transition to novel, more adapted states of organization. Nonlinear pedagogy represents a key principle to create chaos in the performer 'motor system because it challenges the neurobiological system's action degrees of freedom (Schöllhorn et al., 2012). Constraint-led, functional variability, differential learning, and improvisation are examples of evidence-based nonlinear methods that have been associated to motor and tactical creativity enhancement.

Constraints-led training stimulates the discovery of a myriad of movement solutions or benefit a deeper investigation of a fewer ones (Orth et al., 2017). By manipulating individual, environmental and/or task parameters according to the unique performers initial characteristics, it induces uncertainty leading to a reorganization of strategies to solve motoric problem. For instance, Torrents et al. (2015) explored the effect of evolving constraints on 3 pairs of contemporary dancers. While dancers were free to move in any way they wanted with their partner in the first condition, they were instructed to keep their pelvis as close as possible in the second condition and as far as possible in the third condition. Results indicated that task constraints had a significant effect on the type of configurations performed by the dancers. The capacity to vary motor behavior without compromising its functionality improved under similar constraint conditions in several sports.

Functional variability implies changing the task (e.g., random practice) or the context (e.g., context interference approach) from one repetition to another to force constant cognitive reconstruction triggering the instigation of different solution pathways. In boxing, for instance, continuous subtle changes in the scaled performer-target distance led to spontaneous and novel striking techniques that had not been practiced or taught before (Hristovski et al., 2011). Adding movement variability in soccer drills targeting passing and shooting skills also triggered substantial positive alterations in motor behaviors (Schöllhorn et al., 2006).

Considered highly nonlinear because the performer's motor actions are constantly challenged by stochastic perturbations, *differential learning* does not identify key task constraints. Instead, it amplifies preexisting fluctuations in the performer's subsystems to initiate self-organization processes and allow the emergence of novel and more effective movement patterns (Schöllhorn et al., 2012). Different programs asking performers to display movement under constant perturbations (e.g., eye closed, hand tied, variation in ball size, etc.) in random order impacted positively creative behavior and technical game performance in other performers.

The unexpected facet of differential learning is comparable to the demand of improvisational activities. Being one of the most complex form of creative behavior (Santos et al., 2016), improvisation forces individual to break away from pre-established patterns. Inspired by *Cirque du Soleil* artistic classes, improvisation techniques were employed to help elite figure skaters free up their performance. Not only quantitative measures of creative attitudes and values improved, but skaters reported being more open-minded and willing to take risks following the intervention (Richard et al., 2017). Similar effects of improvisation was also observed in dance.

Integration of the nonlinear methods resulted in designing programs aimed at enhancing kinesthetic creativity in children. Firstly, the Skills4Genius program showed that by integrating problem solving, diversification, ludic fundamental skills games, and moderate contextual interference children stretched both creative thinking and in-game individual creative behaviors (Santos et al., 2017). On the other hand, Creative Champions metamorphosed a conventional fitness program into a more creative one. The use of constraints, variability, fantasy play, problem solving and improvisation to encourage children to move differently resulted in significantly more original thoughts, as well as fluent and flexible movements compare to

the children that continued the conventional exercise program (Richard et al., 2018). The impact of a creativity supportive environment on the fluency, flexibility and originality of movements and tactics may be mediated by affective variables which are reviewed next.

Affective Resources

Laborde and Raab (2013) compared the impact of positive and negative moods on the option-generation process in handball players of different expertise levels. The absence of significant interaction between mood and the number of option generated by players contradicts previous evidence stating that positive mood affects the way people make decision. The fact that only hedonic tone was considered to assess mood can in part explain this discrepancy. In addition to the positive and negative characteristics of mood, regulatory focus and activation are highly influential in idea generation process. Positive mood combined with promotion focus has shown the strongest positive association with creative behaviors.

In this vein, researchers examined whether priming promotion or prevention regulatory focus influence sport-specific creative solutions in a dynamic video soccer task (Memmert, 2015). Promotion focus refers to attending to accomplishments and aspirations whereas a focus on safety and responsibility is labelled prevention focus. Findings revealed that athletes in a promotion mode produce more adequate, original, and flexible tactical solutions than those in a prevention one. Social prime was also used to test whether listing the characteristics of a creative soccer player (e.g., Lionel Messi) or a non-creative one (e.g., Per Mertesacker) was activating cognitive concepts associated with creative response tendency when performing a soccer decision making task. Interestingly, neither mood nor motivation were significantly influenced by social prime. Yet, athletes that described the creative player exhibited substantially more fluent and flexible decisions in the soccer task than the one primed with the non creative player thereby confirming the cognitive activation hypothesis (Furley and Memmert, 2018).

Personality is considered as an additional affective resource associated to creativity. For instance, Fink and Woschnjak (2011) demonstrated that modern/contemporary dancers, who presented a greater creative potential, were somewhat more open to experiences than ballet dancers and less conscientious than both jazz and ballet dancers. The discrepancy in personality traits expression between these different groups can be attributed to environmental conditions. The adherence to strongly predefined scripts in ballet may account for the low level of creative traits exhibited by these performers.

Conclusion

To conclude, the increasing number of scientific work targeting creativity in the motor domain over the last decades point towards the importance of nurturing motor and/or tactical creativity to optimize performance throughout the athletic development. Although cognitive and ecological dynamics frameworks dominate the literature, more research must be conducted to confirm the pathway of creativity occurrence. Nevertheless, setting appropriate environmental conditions and triggering optimal cognitive and affective resources are promising solutions to foster creativity in performers. By unleashing their motor and/or tactical creativity, performers make sports more exciting and performing arts more aesthetically attractive (Hristovski et al., 2011).

Introduction

The relationship between stress and creativity is complex. Variations in findings have elicited positive (e.g., Baer, 1998), negative (e.g. Amabile et al., 1990), and curvilinear (e.g., Landon and Suedfeld, 1972) relationships between stress and creativity. Context has also been found to impact the influence of stressors as demonstrated in studies of workplace stress, which found that idea generation was impacted by the meaning derived from the work as seen from the employee's perspective (Ren and Zhang, 2015). Our busy lives are constantly bombarded by varying types and degrees of stressors that affect our productivity at work, in school, and at home. This entry begins with a review of the research on creativity and stress from three viewpoints found in the literature, ways in which stress increases creativity, how stress decreases creativity, and how stress can activate and increase creativity to a point, with too much activation diminishing creative output. The entry will conclude with research examining developmental aspects of this debate, adaptability, and the effects of the internet on perceived stress and its relationship to creativity.

Models of the Relationship Between Stress and Creativity

As a precursor to the review of various theoretical models and their explanations of the relationship between stress and creativity, a definition of terms will be provided. In a review of workplace stress and ideation, Byron et al. (2010) used a stimulus definition of stress, emphasizing a focus on stressors, including physical (e.g., noise), or psychological (e.g., evaluation) conditions that require an adaptive response. Though creativity involves both an emphasis on process and product, this entry focuses on the product aspect to address how stress impacts productivity—the production of ideas, solutions, or products that are novel and appropriate in a given situation.

Theories in support of the perspective that stress reduces creativity include distraction arousal theory which suggests that individuals have limited mental resources and that stressors use a portion of these resources leaving fewer mental capacities available for use to complete the task at hand. More complex problem solving techniques are perceived to be used first, leaving more simple mental abilities to be used later (Teichner et al., 1963), as in narrowed attentional focus (Eysenck, 1995). The simple mental abilities are thought to limit the novelty of problem solutions, thus reducing creativity (Baron, 1986).

In the context of creativity in the workplace, factors such as chronically high workload pressures have been reported as harmful to creativity (Amabile et al., 1996). Chronically high workload pressures exist in environments that regularly involve mindful and cognitively challenging tasks, have high imposed time pressures for task completion, frequent interruptions as multiple tasks compete for priority, and reduced control over timing, pacing, and quality of work product as supervisors rearrange schedules to make up for time deficiencies. Hallowell (2005), a psychiatrist, asserted that organizations may be in a state of experiencing long-term underperformance and lack of creativity due to chronic stress and intense workload pressures. In studies of workplace stress and creativity, he also found that chronically over worked employees were starting to exhibit signs of an attention deficit trait—a state typically characterized by “distractibility, inner frenzy, and impatience”—completely caused by one's environment (compared to attention deficit disorder symptoms caused by both physiological and genetic components) (Hallowell, 2005, p. 1).

These high workload contexts would qualify as both high in job demand and low in job control, components of models of job strain (Karasek, 1979). Likewise, the cognitive constraints and diminished creativity of environments impacted by employees' belief that they have little control over their work environment can be compared to individuals living in high crime, high poverty neighborhoods where many stressors have been found to decrease creativity as a results of residents believing that they have little control over their circumstances (Porter, 1995, 1998; Chand O'Neal et al., 2020).

Theories emphasize the finite cognitive resources available for problem solving, underscoring that dealing with the pressure of a tight deadline, or challenges with a colleague, drain a great deal of the cognitive resources leaving little energy left to finish the work. How does a company create the ideal work environment offering challenging tasks with little external stress? One answer has been the recognition by employers that work stress can take a toll on productivity. To address this burden, companies are encouraging workplace wellness to combat workplace stress. Emerging in a number of highly productive companies are such

initiatives as revamping work habitats, allowing for flexible hours and remote working, providing opportunities for socializing with colleagues, providing onsite and distance counseling, and recognizing employees for exceptional work.

The expression, “Necessity is the mother of invention,” is based in the perspective that stress increases creativity. This viewpoint is supported by studies on arousal, which suggest that stress increases arousal which stimulates the use of creative thought to devise solutions. For example, in a review of studies on innovation in the workplace, [Anderson et al. \(2004\)](#) found that such stressors as job dissatisfaction, negative mood states, unsupportive coworkers, task conflict, and home and work strain increased creativity, suggesting that stressors create a demand for creative solutions while simultaneously providing the cognitive stimulation and motivational arousal necessary for creative thinking ([Andrews and Farris, 1972](#); [Pelz, 1988](#), [Chand and Runco, 1992](#)). Zhou and Shalley (2003) identified specific dimensions of work environments that increased intrinsic motivation, and thus increased creativity in professionals. These dimensions included: challenging and complex jobs, the presence of creativity goals, and developmental (versus controlling) feedback, which [Amabile \(1996\)](#) termed environmental stimulants to creativity.

These studies demonstrate the effect of stressors as a motivating factor, activating the instinctual response to resolve cognitive dissonance and find ways to better the environment and improve the circumstances, or remove oneself from the source of the discomfort as quickly as possible. How often have you found yourself in a traffic jam, searching your memory (or apps) for ways to find a shorter, less congested route? How about realizing that a necessary ingredient for a recipe is missing while in the middle of preparing a meal, and substituting it with something on hand? In each of these examples, the stress caused by the unpleasant situation – a traffic jam or missing ingredient – generated divergent thinking which might result in a creative response.

Scholars who proposed a curvilinear relationship between stress and creativity asserted that activation theory explains how creativity is stimulated by stress only to a point; after which creativity begins to decrease ([Gardner, 1990](#)). According to this perspective, individuals are most creative at moderate levels of activation, because moderate activation levels facilitate optimal use of cognitive resources, increases task engagement, and decreases negative affect, while also increasing positive affect ([Baer and Oldham, 2006](#)). Too little or too much activation leads to a lack of engagement and cognitive interference which can diminish creative performance on cognitively demanding tasks. In addition, the effects of stressors are not the only factors to influence creativity; in the case of a curvilinear relationship, the type of stressor may also impact creative outcomes. [Byron et al. \(2010\)](#) identified social-evaluative threat and uncontrollability as possible influencing stressors that may affect different aspects of the self, which may be differentially associated with the cognitive and motivational mechanisms underlying creativity.

Social-evaluative threats can occur when an aspect of self can be judged by others, causing a decrease in creativity as a result of the increase in efforts to preserve the self. Most people have experienced classroom scenarios in elementary or high school where the teacher asked for ideas on how to solve a problem. In some cases, when a student felt confident in his or her mastery of the subject, ideas were abundant; however, when confidence of skills in the area were low, in an effort to preserve themselves, students may have experienced a decrease in divergent thinking and diminished creative ideation.

Adaptability and the Effects of Stress on Creativity From a Developmental Perspective

The three perspectives previously described address an underlying theme of adaptability. In order to be creative, one needs to be cognitively nimble, sensitive to the needs of a situation, and able to devise solutions that may need to be adjusted during any stage of solution implementation. The previous discussion focuses on examples of how stress influences creativity in the workplace; however, experiences with stress and performance emerge long before individuals become employed. Studies examining the relationship between creativity and stress from a developmental perspective suggest that the family dynamic is among the first introductions to how one must learn to adapt in order to address wants and needs. Researchers reported that stress during childhood may contribute to the development of creative skills. [Albert \(1978, as quoted in Runco, 1999\)](#) found that

the creative person to be comes from a family that is anything but harmonious—one which has built into its relationships its orientation of roles and its level of communication a good deal of tension if not disturbance, what I call wobble, but along with these characteristics, there is commitment to achieve as opposed to “having fun,” a special focus of interest and aspirations upon the child and a great deal of family effort to see that these aspirations are met.

Albert (1978, pp. 202–204)

Another type of stressor within the domain of family dynamics was identified by [Albert and Runco \(1989\)](#) who found that some parents of exceptionally gifted children are aloof, creating a distance that at first may cause stress for the child; but that may ultimately promote a sense of independence, exploration, nonconformity, and risk-taking—all hallmarks of creativity. Albert and Runco further highlight that there is an optimal amount of distance, and that autonomy and nonconformity are not characteristics that parents should maximize since it is not guaranteed that autonomy and nonconformity will result in creativity; in some instances the result is serious social and emotional disturbance.

[Winner \(1996\)](#) conducted studies with gifted youth and posited that children who experience stress may retreat into “an obsessive, solitary focus on an area of talent Hardship could teach lessons in perseverance and resilience, two ingredients needed for

later creativity" (p. 300, as quoted in [Runco, 1999](#)). Her work also emphasized that stressful experiences could serve to increase a child's comfort or willingness to be different.

Birth order raises an interesting issue in the quest to better understand the relationship between stress and creativity. Some studies concluded that firstborns suffered greater anxiety and fear of physical injury ([Helmreich and Collins, 1967](#); [Nisbet, 1968](#)). In contrast, [Eisenman \(1987\)](#) found that firstborn males were greater risk takers than their later-born peers, raising the possibility that ultimate pay off or reward may shape how stress ultimately influences creativity. [Sulloway \(1996\)](#) offered yet another perspective on birth order drawing on the work of Darwin, suggesting that siblings must compete for resources. This competition and struggle is clearly a source of stress placed squarely on each sibling to develop strategies to be in favor with their parents, or find a unique niche within the family structure. Sulloway further posited that firstborns use adaptability to adjust to the birth of their siblings relying on strategies that cannot be used by their younger siblings, simply because they do not have the same goals of aligning with their parents. Younger born siblings, instead, strive to create their own position in the family dynamic by developing strategies of their own to be different from other family members, which often results in rebellion.

The Effects of Internet Use on Perceived Stress and Creativity

The widespread use of information and communication technology (ICT) has become a part of daily life. While the use of ICT demonstrated benefits for psychological health and well-being, including the acquisition of online social capital ([Ellison et al., 2014](#)), or the support of intrinsic needs ([Reinecke et al., 2014](#)), the effects of communication load and internet multitasking are another set of stressors to be considered from a developmental perspective.

Internet users of all age groups appear to be constantly connected to a stream of online content and computer-mediated communication ([Vorderer and Kohring, 2013](#)). Young children often begin with short online games and the streaming of 11-min episodes, graduating to hours of video games and close to constant social media engagement in early adolescence. Many young people are stressed by fear of missing out and the social expectations to respond to online communication. The influence of social pressure on behavior is particularly pronounced for adolescents and young adults and has been shown to decrease in adult life ([Steinberg and Monahan, 2007](#)). The sheer mass of communication content, as well as the increasingly popular trend of combining internet use with other simultaneous activities exposed users to information overload and impaired their psychological well-being ([Misra and Stokols, 2012](#)).

In a study examining the effects of digital stress across the lifespan with participants ranging from ages 14–85, [Reinecke et al. \(2016\)](#) found that communication load resulting from sending, receiving, and checking private emails and social media messages, as well as internet multitasking were significantly related to perceived stress. In addition, the indirect effects of communication load and internet multitasking on burnout and depression and anxiety demonstrated that the potential health impairments resulting from the private ICT—strain extended to decreased levels of psychological well-being. The comparison of the three age categories (14–34, 35–49, and 50–85) suggested that older individuals were better at coping with internet multitasking than younger users, which could be explained by the process of accommodation.

As seen in prior research on aging and cognitive ability, older individuals engaged in various strategies to compensate for age-related decreases in cognitive capacity, including the avoidance of deficit-revealing situations ([Salthouse, 2012](#)). In the case of Internet multitasking, this could imply that older adult users more actively avoid situations in which multitasking exceeds their cognitive capacity by choosing concurrent activities that require low cognitive demand. Such accommodation strategies may be used less frequently with regard to communication load as users have limited control over incoming messages and the necessity to respond. Though this study did not examine creativity directly, the findings highlighted that strain from private computer-mediated communication has similar effects on psychological health and well-being as ICT-related information overload in the workplace, which parallel earlier discussions regarding the effect of cognitive demand as a stressor effecting creativity.

Summary and Conclusions

What are the implications for the connections between stress and creativity? Early in the chapter, three relationships were identified: the role of stress in decreasing creativity, increasing creativity, and that stress increases creativity to a point; with too much activation and/or social-evaluative threat causing cognitive overload, thus eventually decreasing creativity. This curvilinear relationship was found to most accurately represent the complex relationship between stress and creativity, as indicated by findings of the meta-analysis of competing theoretical models of the relationship between stressors and creativity ([Byron et al., 2010](#)). Key findings emphasized the importance of perceived stress, how stress-inducing the stressor is, and at what developmental timeframe it emerges. Tension to a degree, serves to spark creative thinking; while an excess causes cognitive overload and diminishes creative ideation. Developmental themes addressed the role of birth order in honing specific creative skills through competition, acknowledging that this tension is an important component of what motivates action. And finally, the effects of digital stress on creativity were discussed in the context of cognitive load that varies by age.

The perspectives discussed in this entry move well beyond examining the general nature of the relationship between stress and creativity to highlight inconsistent findings regarding how different stress stimuli effect creativity under varying conditions and at differing points across the lifespan. The themes discussed underscore that the relationships between stress and creativity are complex

and may not be adequately captured by merely describing them as positive or negative. Future investigations should further illuminate these relationships by exploring promising mediators and moderators to determine for whom and under what conditions stress affects creativity.

Introduction

Suicide is a multifaceted public health problem of global significance. Almost 1 million people die every year from suicide which means that one person deliberately kills her/himself every 40. Throughout history, anecdotes of creative individuals, and in particular writers, being more inclined toward suicidal ideation and acts have resurfaced and reinforced a notion that creativity may be associated with increased risk of suicide. This chapter examines the current evidence underlying this notion and discusses why such an association could exist.

Suicide—Definitions and Epidemiology

Suicide is the act of a person intentionally ending one's life, whereas suicidal behavior refers to both thoughts and behaviors related to this act. These behaviors include specific measurable outcomes such as suicidal ideation, suicide plans, and suicide attempts. The difference between suicide ideation and suicidal plans is that plans include the formulation of a specific plot by which the individual plans to perform a suicide attempt. Suicide attempts require a self-injurious behavior in which there is at least some intention of dying as a result of this behavior, thus, contrasted with non-suicidal self-injury where there is no intent to die.

An investigation of 17 countries demonstrated that the lifetime occurrence of suicide ideation is 9.2%, plans 3.1%, and non-lethal attempts 2.7% (Nock et al., 2008). More recent data from 2016 in the Global Burden of Disease Study emphasize the large variability of suicide mortality across regions ranging from 4.8 per 100,000 in North Africa and Middle East to 27.5 per 100,000 in Eastern Europe. But, regardless of the considerable difference between locations in terms of the prevalence, once established the characteristics of suicidal behavior are fairly consistent across different countries. For example, the onset of suicide ideation increases dramatically during adolescence, and about a third of people with suicide ideation will go on to make a suicide attempt, and more than 60% of these attempts occur within one year of the onset of suicidal ideation.

Suicide—Risk Factors

The underlying causes of suicidal behavior remains elusive, but several risk factors have been identified. There is an increased risk for non-fatal suicidal behavior among unmarried, socially disadvantaged (e.g., low income and education, or unemployed), young people, and women. Men are more likely to die by suicide. The global male:female ratio is 1.7, which means that men complete suicide almost twice as often as women. In high-income countries this ratio is increased to 3.5 (Turecki and Brent, 2016). Certain occupational groups have also consistently been demonstrated with increased risk for suicidal behaviors. These include an increased

risk in lower skilled occupational groups (possibly symptomatic of social and economic disadvantages), and among those with easier access to means for lethal suicide such as farmers, police, military and medical professionals.

Psychopathology Is the Main Risk Factor for Suicide

One of the most researched risk factors for suicide is psychopathology (mental illness). Findings based on psychological autopsy using a combination of interviews and corroborating evidence from sources such as hospital and general practice case-notes, social work reports and criminal records, suggest that 90% of people who die of suicide have a psychiatric disorder, although a recent review stressed that there is considerable heterogeneity in different parts of the world with the prevalence of any mental disorder among suicide victims in East Asia (70%) was markedly lower than in North America (88%) and South Asia (90%).

Depressive episodes in patients suffering major depressive disorder or bipolar disorder account for at least half of suicide deaths, with a 20-fold increased risk. Suicides are completed by 5%–14% of all affected individuals with schizophrenia. There is some confusion about substance use disorders, as these are sometimes reported separated from other mental disorders, but in outpatients substance related disorders represent the second most common reason (22.4%) for completing suicide. In high-functioning (i.e., no co-existing intellectual disability) autism, a 10-fold increased risk of suicide was reported in a Swedish national sample. Studies also demonstrated a marked increased risk of suicide in eating disorders both in young adults and patients aged 25–44 years.

Is There an Association Between Suicide and Creativity?

Many famous creative individuals have committed suicide, and often stories of these individuals have served to uphold a perception of creativity as unambiguously intertwined with suffering and drama aptly captured by the writer Red Smith: "There's nothing to writing. All you do is sit down at a typewriter and just open an artery." (Abra, 2015, p. 25). Scholarly work on creativity and suicide has followed a number of themes including the meaning of suicide in art, case studies of artists who committed suicide such as Sylvia Plath and Vincent van Gogh, and increasingly using a quantitative approach targeted at both eminent individuals and those in creative occupations overall (Stack, 1996).

Researchers began to gather samples of creative and eminent individuals to understand more about the nature of geniality in the early 20th century. Ellis studied 1030 British geniuses (1904), Lange-Eichbaum (1928) sampled 800 historical geniuses, and Juda (1949) focused on artists by investigating 113 notable German artists and 181 scientists from the period 1650–1900. The common conclusion of these authors was to question earlier proposals of geniality being necessarily associated with madness as forcefully proposed by Cesare Lombroso in 1891. Juda (1949) found that 2/113 (1.8%) of the artists investigated committed suicide. Stack (1996) noted these results were similar to US data for American males in 1990 (1.76%); however, he also concluded that given the historical perspective, suicide was likely far less common in the period of Juda's investigation (1650–1900).

Ludwig (1992) investigated 1005 prominent individuals whose biographies were reviewed in the New York Time Book Review 1960–90, and found that those engaged in theatrical professions, writers of fiction and poets demonstrated comparably high rates of suicide attempts. Another study of 291 world-famous men, based on those judged to have achieved lasting international fame for their impact in a variety of fields, found five cases of completed suicide (Ernest Hemingway, Ludwig Boltzman, Vincent van Gogh, Adolf Hitler, and Pyotr Tchaikovsky), and a total of 22 suicide attempts. Writers most frequently exhibited suicidal behavior with 16% having made a suicide attempt.

Preti et al. (2001) investigated a sample of 4564 eminent artists who died in the 19th and 20th centuries. Eminence was defined as those whose achievements rendered an inclusion in an established encyclopedia for art, literature, and music. The sample consisted of 2259 poets and writers, 834 visual artists, and 1471 artists involved in musical activities. There were 63 suicides in the sample (1.3%). Literary artists stood out (2.3%), and specifically female literary artists (4.3%). Female poets were at the highest risk with 6 out of 42 (14%) committing suicide (Lester and Krysinska, 2011). Musicians and composers (0.2%) as a group had lower suicide rates than the literary and visual artists (0.7%). It was suggested that this could be due to several reasons, such as that a musical occupation generally involves more social interaction and better opportunities for employment than a literary and visual arts career. In addition, developing a skill for music requires technical skills and constant social interaction which would be difficult to acquire for individuals with severe mental disorders. Finally, the researchers proposed that the musical activity in itself could have a therapeutic effect.

Stack (1996) studied artists based on occupational data in 21 US states. The study was limited to the working-age population aged 21–64. The sample consisted of 6198 suicides and 8827 natural deaths during 1990. Artists were defined as authors; musicians and composers; actors and directors; painters, sculpturers, craft artists, artist printmakers and dancers. Results demonstrated that artists had about 125% increased risk of suicide compared to non-artists when adjusting for age, gender, and race.

Stack's findings could not be corroborated in a Swedish total population study including a sample of patients with psychiatric disorders and data on all completed suicides in Sweden 1952–2009 (Kyaga et al., 2013). Information on occupation in this study was gathered through national mandatory self-report questionnaires completed by all adult citizens in 1960, 1970, 1975, 1980, 1985, 1990 and through a national register from 2001–09. Artists as a group demonstrated no increase in completed suicides (Odds ratio 0.93 (0.86–1.01)) compared to matched controls. However, as previously suggested by Ludwig and Preti et al.

when only analyzing authors there was around a 50% increased risk of suicide. Performing artists and directors also demonstrated a significant increased risk of suicide of about 30%. In line with Preti et al. results, visual artists displayed a lower likelihood of suicide than authors, and musicians and composers even lower than matched healthy controls. Scientists had less than half the risk of suicide compared to matched controls. The reported results of this study may be conservative estimates as it only included what was considered as “certain suicides.” When also including what was labeled “uncertain suicides” the risk of suicide for authors increased to about 90% and for performing artists and directors to around 50%.

Finally, a recent report by the [British Office for National Statistics \(2017\)](#) analyzed suicides by occupation in England from 2011–15 and found an increased risk of suicides in both males (~38%) and females (~112%) working in artistic, literary and media occupations. Contrary to recent investigations, musicians were found to have the highest risk of suicide (males (~152%), females were too few to report), followed by actors, entertainers and presenters (males (~141%). Females had few cases but were reported, whereas neither male or female authors, or writers and translators had a significant increased risk of suicide. It is not clear if the latter findings were due to a broader definition of writers than previously used in other studies.

Is There an Association Between Psychopathology and Creativity?

Given that 90% of people dying by suicide have a concurrent psychiatric disorder, it is pertinent to consider if an increased risk of suicide in creative individuals is mediated by increased psychopathology in this group. Suggestions that creativity and geniality are related with eccentricity and even madness has a long history. Often referred is Aristotle's (384–322 BCE) question placed in *Problematika XXX*, written by his pupil Theophrastus (371–287 BCE), “Why is that all those who have become eminent in philosophy, politics, poetry, or the arts are clearly melancholics and some of them to such an extent as to be affected by diseases caused by the black bile?”

In 1987 Andreasen, interviewed 30 creative writers at the University of Iowa writers' workshop, and compared those to healthy controls. She found increased risk for affective disorders (depression and bipolar disorder) in general and for bipolar disorder in particular. Similarly, Jamison found increased risk for affective disorders in 47 British writers (1989). Ludwig found an increased occurrence of bipolar disorder, schizophrenia-like psychosis and depression in the creative arts group compared to general population means.

These three studies have been criticized by some authors questioning the association between creativity and psychopathology. [Schlesinger's \(2012\)](#) criticized the authors of these studies for both selecting study subjects and making the diagnoses themselves. This would render the results open to both bias and hamper generalization. While aspects of Schlesinger's criticism is relevant, she didn't mention the other roughly hundred empirical studies investigating the association between creativity and psychopathology that address many of the previous limitations.

Different Types of Creative Expressions

As has already been described, the type of creative occupation, i.e., being a writer, an actor, a visual artist, a musician, or a scientist seems to be related to the risk of suicide differently. In general, studies suggest that writers and specifically poets are most at risk for suicide. There are several reasons why this may be the case. In general, literary work is done in solitude and with lack of continuous gratification compared to performing and visual arts. The latter could also lead authors to depend more on leisure activities as a source of immediate satisfaction, which in turn could promote a less healthy life style. Similarly, as suggested by Preti and colleagues it may be more difficult to maintain employment as a writer than in other creative professions (2001) and other creative expressions such as music requiring technical skills could be difficult to acquire for individuals with severe mental disorders. This is certainly corroborated in the studies by [Kyaga et al. \(2013\)](#), where authors had an increased risk for schizophrenia, bipolar disorder, unipolar depression, and many other psychopathologies. However, musicians did have an increased risk for bipolar disorder.

In fact, studies have also suggested that different psychopathologies may be more or less prevalent pending on the creative expression. Examination of the healthy siblings of patients with schizophrenia, bipolar disorder and autism in the total population data provided by [Kyaga et al. \(2013\)](#) indicated that these disorders differ in the likelihood dependent on what type of creative expression is being investigated ([Fig. 1](#)). There was a trend toward increased occurrence of artistic professions more than scientific professions in siblings of patients with schizophrenia, and conversely scientific occupations being more pronounced in siblings to patients with bipolar disorder and autism.

Suicide—Theoretical Model

The causes of suicidal behavior are still not fully understood; however, it is clear that there is a complex interplay between different factors. Today, suicide is often considered within a diathesis-stress framework. This posits that pre-existing vulnerability factors are pronounced when activated by stressful events. The factors associated with suicide risk can broadly be categorized along three different dimensions: personality and individual differences, cognitive factors, and social factors. Some of these factors may contribute to the emergence of suicidal ideation, whereas others may increase the risk of suicidal acts.

Figure 1 Study on ~1.2 million patients indicating a trend toward increased occurrence of artistic professions more than scientific professions in healthy siblings of patients with schizophrenia, and more pronounced for scientific professions in healthy siblings to patients with bipolar disorder and autism. An odds ratio (OR) higher than 1 implies an increased occurrence compared to matched controls (Kyaga et al., 2013).

Personality and Individual Differences

Biology

Suicidal behavior runs in families. It is unlikely that this is only due to imitation, as adoption studies support concordance between biological, but not between adoptive relatives. Overall, the proportion of variance explained by additive genetics for suicidal behavior has been assessed at 30%–50%. Interestingly, suicide ideation seems to be transmitted with mood disorders and show a distinct pattern of transmission of suicidal behavior. Many authors have concluded that creativity, mood disorders and suicide run alongside in families.

Personality Traits and Attitudes

Hopelessness can be viewed as both a state (changing over time) and trait (relatively stable over time) factor. It has been defined as pessimism for the future, and is a strong predictor of important aspects of suicidal ideation and behavior (O'Connor and Nock, 2014). A 10-year prospective study of patients admitted to hospital for suicide ideation was able to predict 91% of all cases of suicide from scores on hopelessness.

Perfectionism has increasingly been identified as a risk factor both for suicidal ideation and suicide attempts. Specifically, socially prescribed perfectionism where there is a belief that other people hold unrealistic high expectations may be the most detrimental type of perfectionism and has consistently been linked to increased risk of suicide. One of the reasons for this is that it promotes social disconnection, and also interacts with other factors such as negative life events.

Impulsivity has been studied intensively as a risk factor for suicide and self-reported impulsivity is associated with suicidal ideation, suicide attempts, and suicide deaths (O'Connor and Nock, 2014). It is still considered a risk factor though it has been noted in recent studies that different definitions of impulsivity rendered paradoxical results.

There have also been several studies reaffirming that specific aspects of the big five personality dimensions may be linked to increased suicide risk. This is most evident for high levels of neuroticism and low levels of extraversion, in particular when combined. These findings fit with the diathesis-stress framework, proposing that some people are more vulnerable by being more sensitive to distress (high neuroticism) and socially disconnected (low levels of extraversion).

All of the above factors can be conceived in creative professionals. Even established artists and scientists, face a frequent risk of rejection of work that they are personally vested in (Stack, 1996). This is even more pronounced in work dependent on countless hours of solitary work where no coauthors will share the rejection, such as in literary work. It is not unreasonable that those individuals, whose work is rejected, will exhibit feelings of hopelessness. Increasingly, creative professionals also face the risk of evolving

socially prescribed perfectionism supported by ever more pervasive reviewers. Finally, a meta-analysis on the personality of artists and scientists concluded that they exhibit both introversion and impulsivity to a larger extent, and that artists were especially prone to anxiety and emotional instability. A study of creative college students also suggested that these perceived suicide as both a more normal behavior and judged it to be less of a moral evil compared to non-creative peers (Lester and Kryszyska, 2011).

Cognitive Factors

Several cognitive factors predict suicide risk. This is not least evident for cognitive rigidity, rendering the individual conceiving suicide as the only possible outcome (O'Connor and Nock, 2014). One study of 81 college students demonstrated that while ideational fluency may be positively associated with suicide ideation, problem solving flexibility is negatively correlated with suicide ideation suggesting that suicide ideation is a reaction to the tendency to see a large number of personal problems while having few adaptive solutions (Mraz and Runco, 1994). To further aggravate this tendency, Runco (1998) in his analysis of Sylvia Plath proposed that for the creative individual, with time, the more he or she has invested in creative endeavors the more he or she has to lose and thus will increasingly be less likely to remain flexible to new solutions. Cognitive rigidity remains a risk factor regardless with or without the presence of depression (O'Connor and Nock, 2014). Other factors are rumination referring to the repetitive focus on an individual's own symptoms of distress, and lack of interpersonal problem solving. Perceived stress could indeed result from poor problem solving by interpreting a situation as problematic when there is no apparent solution available (Mraz and Runco, 1994). Rigidity, rumination and lack of interpersonal problem solving are all common symptoms in persons suffering from a depressive episode. Behavioral rigidity and lack of interpersonal problem solving also remain core features of autism without depression.

Social Factors

Suicide occurs in a social context. Both social isolation and lack of social support are established risk factors for suicide (O'Connor and Nock, 2014). Suicide is rare in homogenous societies with high social cohesion, common values, and moral objections to suicide (Turecki and Brent, 2016). Increases of suicide rates among indigenous peoples correlate with social changes such as forced settlement and disruption of traditional structures. Economic crises resulting in unemployment and reductions in personal income has been correlated with suicide specifically in men. Finally, media reporting of suicide, especially if the individual who committed suicide is a celebrity and the reports of the suicide were romanticized has been associated with a rise in suicide proportional to the publicity received. This is the so called Werther effect derived from the publication of Goethe's "The Sorrows of Young Werther" in 1774, which allegedly led to young lovers committing suicide in imitation.

As previously discussed, many creative professionals face a difficult and insecure economic situation and lack of social support. In addition, it is possible that artists and maybe specifically authors are more exposed to and engage in romanticized stories of suicide. This could be one of the explanations why creative college students perceive suicide as a more normal behavior compared to their non-creative peers (Lester and Kryszyska, 2011).

Negative life events both in childhood (for example physical, sexual, and emotional abuse; family violence; and parental illness, divorce, or death) and in adulthood (for example physical or sexual abuse; death of a loved one; disasters or accidents; and exposure to war or other violence) has also been consistently linked to increased risk of suicidal behavior. Studies suggest a dose-response relationship between the number of adversities and ensuing risk of suicidal behavior. Physical and sexual abuse appears to convey the highest risk for suicidal behavior. In parallel, several authors have proposed that numerous eminent individuals faced adversities in early age (Runco, 2014, p. 46), and there is some support that traumatic events may incur increased creativity.

For example, Simonton (1994), reviewed the literature regarding an "orphanhood effect," suggesting that eminent individuals suffered early parental loss at higher rates than the average population. This effect seemed to be more pronounced in writers. Kim and colleagues proposed that for individuals with an independent self-image, rejection may amplify feelings of social disconnection and thereby increase creativity by conferring an inclination to move beyond common knowledge structures (2012). Another study of 376 participants recruited online from different countries (77% from North America, 8% from Europe, 6% from Australia or New Zealand, 4% from Asia, 2% from Africa, and 3% from other parts of the world) linked the experience of adversity with an increase in self-reported creativity (Forgeard, 2013). The findings were suggested to be mediated through both intrusive and deliberate rumination.

Psychopathology as the Main Driver for Suicide

It is certainly feasible to consider how many creative individuals' social situation could incur the main drivers for suicide (O'Connor and Nock, 2014). However, it remains evident that most suicidal patients feel that they are in a life situation with unbearable suffering and without hope for relief, but that their perceptions are often distorted by concurrent psychiatric disorders. Minor physical ailments for example can be insufferable under depression, and terrifying hallucinations may bring considerable suffering for the patient afflicted. There are arguments why primarily addressing psychopathology may be more relevant than considering psychosocial circumstances (Hegerl, 2016). First, psychological autopsy studies show that around 90% of those committing suicide have been suffering a psychiatric disorder. Second, while studies support that economic crisis induced an increase in suicide rates; it is possible that this is in fact driven by a deterioration in care for people with mental illness. This is suggested by data from 29

European countries showing that changes in suicide rates were not related to gross domestic product (GDP), unemployment rate, but to the prescription of antidepressants (Hegerl, 2016). An increase in the rate of prescription of antidepressants was associated with a decrease in suicide rates. Third, after the reunification of Germany in the 1990 there was a considerable change in society with unemployment increasing from 0% to 20%, societal values were changed, and many people with long professional careers saw their work terminated. Nevertheless, suicide rates decreased abruptly in the Eastern part of Germany. Thus, it seems that increased psychopathology may be a significant reason for increased suicidal behavior in creative individuals, and maybe more importantly lack of treatment for depressive episodes and other psychiatric disorders should remain an imperative in the prevention of suicidal behaviors.

Does Treatment for Psychopathology Affect Creativity?

There is support for many different types of interventions to prevent suicide. These include among others school, workplace, and community-based interventions (Turecki and Brent, 2016). Psychotherapeutic treatments for suicidal behavior share several common elements, such as the use of exploratory interventions to understand the reasons for the behavior and interventions to encourage positive and reduce negative behaviors. The therapist generally adopts an active attitude to reinforce problem solving skills.

Problem-solving is often viewed as an important component of creativity, but it has been described as structurally different from creativity and more concerned with the practical operations of seeking solutions to everyday issues. Denzler and Tsakos (2015) suggested that the distinction between the two constructs lie in the process and goal. Creativity is a dynamic process aiming to generate a new idea for an unknown problem. Problem solving, instead, is a rational process that seeks to develop a solution for a known problem. In fact, one study found that art students were more creative but performed less well on a problem-solving measure. While the distinction between creativity and problem solving can be challenged it remains evident that lack of problem solving flexibility is associated with suicide ideation (Mraz and Runco, 1994).

Meta-analyses of randomized controlled trials of lithium, generally used in bipolar disorder, support its protective effect against suicide. Three studies have examined lithium in relation to creativity, although only two provide clear results. Shaw et al. examined the effect of lithium on the productivity and idiosyncrasy of written associations in 22 euthymic outpatients with affective disorder (Shaw et al., 1986). Lithium discontinuation led to a significant increase in associational productivity and idiosyncrasy, while restoration of lithium dosage reversed both these effects. Nevertheless, another study interviewing 24 “manic depressive” artists observed that most ($n = 12$) reported favorable effects of lithium treatment on artistic productivity in the long run (Schou, 1979). Hence, while lithium may decrease associational productivity and idiosyncrasy, it seems that by reducing the rate of detrimental mood episodes the decreases in associational productivity and idiosyncrasy is outweighed in the long run.

Clozapine, an antipsychotic medication used in treatment-refractory schizophrenia has been demonstrated to be associated with a reduction of suicide attempts in naturalistic data compared with patients treated with other antipsychotics. Antipsychotics generally yield their effect by antagonizing dopamine D2 receptors. Thus antipsychotics have been proposed to diminish creative abilities dependent on intact dopamine transmission. To date no study has specifically investigated the effects on creativity by antipsychotics.

Do You Get Less or More Suicidal With Creative Activities?

It is poignant to consider why one should commit to an artistic profession in the first place given the described association to both psychopathology and increased risk of suicide. Clearly, there are many benefits from engaging in creative activities. In general, the beneficial aspects of creativity have been linked to self-actualization. Maslow saw creative expression as inseparable from psychological health, and Rogers suggested that it provides a deeply satisfying feeling to commit to creative activities. A phenomenological study of 11 artists emphasized that engaging in creative activities involved a highly energizing effect of sensing a synthesis of disparate elements, and the feeling of connecting with a deeper, more universal self. It has even been proposed that it is beneficial to work with creative writing and poetry in suicidal clients (Lester and Krynska, 2011), but this remains to be further researched. Nevertheless, art therapy has gained some empirical support as an addition to standard treatment in, for example, schizophrenia, where it has been suggested to be beneficial in addressing otherwise difficult to treat negative symptoms, such as lack of motivation and drive.

Conclusion

This entry examined the evidence underlying a notion of creativity being linked to psychopathology and an increased risk of suicide. It is argued that occupational data support an increased risk of suicide for artists generally, and for authors specifically. Most artists do not commit suicide, and creativity entails many positive benefits that promote better psychological health. Nevertheless, the social situation many artists face may be challenging and there is evidence of an increased prevalence of specific types of psychopathology, such as bipolar disorder, in people with creative professions. These findings highlight the need to provide appropriate support to individuals in need and to commit societal resources in preventive measures to reduce suicidal behavior. Today it remains out of balance considering the size of this challenge.

Introduction

Surprise is a feeling one may experience while reading a novel written by Stephen King, when watching a movie directed by Quentin Tarantino, or when hearing about Stephen Hawking's theory of the universe. Surprise arises when people encounter something unpredictable, unexpected, or unanticipated, all of which then leads to wonder, astonishment, and amazement. Clearly, the unpredictable, unexpected, and unanticipated are associated with creative thinking. Surprise is embedded in the concept of creativity and manifested either as the feeling the audience for creative ideas or products experience or what painters, composers, or authors seek in their creative production. Hence, understanding surprise can contribute to the understanding and assessment of creativity.

Neural Response to Surprise

What happens inside our brains when we encounter novel and unexpected stimuli? Although surprise is considered an emotive state, it has a cognitive aspect that defines surprise as a temporal-based cognitive process of the unexpected, a violation of a belief, or a reaction to a mismatch. Some researchers in neurophysiology study surprise by showing the specific reactions of the brain to unexpected events. For instance, Schomaker and Meeter (2015) cited a variety of sources indicating that strong neural firing and activity are seen when individuals encounter unfamiliar stimuli. Some areas, including the limbic regions; frontal cortex; and temporal, parietal, and occipital areas are activated during the state of surprise. In their 2015 book, *"Surprise: Embrace the Unpredictable and Engineer the Unexpected"*, Tania Luna and Leeann Renninger stated that a "surprise sequence" occurs in the brain during the moment of surprise. The neurological system is alerted and focuses on the moment. This first reaction is followed by a cognitive effort to figure out the unexpected stimuli. Finally, in some cases, surprise forces changing one's personal perspectives: imagine you have found a new recipe positively surprising with an ingredient you normally do not like, which in turn changes your perspective about that ingredient.

Surprise process in brain have been the subject of experimental studies. In an early study, Wulf-Uwe Meyer et al. (1997) conducted an experiment to explain the mental process and sequence that occur during the event of surprise. Interestingly, they showed that a cognitive evaluation of an event that exceeds an amazement threshold value is the first step of the mental process. This ongoing process occurs through the breaking off of personal experience and information in memory and distributing resources to the unexpected event. The last step is to undertake the analysis and evaluation of the event and develop an immediate response and belief revision. Their study implies that surprise facilitates the stimulation of adaptive actions to surprising events and developing predictive and useful reactions in case the person experiences the same thing in the future.

Schomaker and Meeter also pointed out that unexpectedness could manifest in different forms, and the brain shows varied reactions depending on the form of unexpectedness. Although it is relatively less common, people may experience something never encountered before, thus feeling highly surprised, such as a first reaction to virtual reality or seeing an unusual art piece. Surprise also occurs depending on certain contextual factors. Seeing a sculpture in a museum is a common experience, but an underwater museum exhibiting sculptures is surprising even though the concept of "museum" and "sculpture" are familiar for most. Next, regardless of the stimuli, the same thing could lead to two different experiences in two different environments. An identical meal could be perceived as more or less delicious or more or less novel in different environments, such as a restaurant and a state park (the latter could be more surprising to an individual). Lastly, deviance among a group of known stimuli might be perceived as surprising. For instance, a dog picture in a series of cat pictures could make someone surprised. Interestingly, brain imaging studies indicate that different parts of the brain are activated under different surprise condition.

Emotions and Creativity

Emotions are likely to take part in creative activities. In other words, the creative process is not purely cognitive; it both influences and is influenced by emotional states. Surprise is inherently part of the creative process. When considering the definition of surprise, there is an association between the level of surprise and creativity that more a creative product is, the more people feel surprised. Emotions are part of the process of the assessment of creativity such that surprise and related emotional reactions determine the degree to which a creative product is deemed novel, unusual, and unexpected.

Both positive and negative feelings, such as happiness, enjoyment, surprise, sadness, anger, and fear, play an important role in creativity. Research studies on eminent creativity have indicated that a considerable amount of eminent artists displayed affective disorders. Hence, the “mad-genius hypothesis”, concerning whether psychopathology is correlated with creativity, is still a continuing controversy in creativity research. Apparently, a good amount of exploratory work supports the association between creativity and negative emotions. Especially regarding the “dark side of creativity”, it is more obvious that negative emotions motivate people to use their creative potential for nefarious purposes. Despite the extended literature on the issue, the “mad-genius hypothesis” is highly questionable, and currently a paradigm shift considers creativity as a type of healthy behavior rather than a deviant one associated with mental and emotional disorders. It is also not surprising that positive emotions facilitate mindfulness, breadth, and flexible thinking.

In the context of creativity, surprise can be described as the emotive moment when people engage in creativity. Amazement, surprise, and excitement are some of the emotions that arise in cases of unexpectedness. Margaret Boden (2007) addressed the issue and indicated that such emotions are a visible aspect of the creative process beyond the cognitive part. In fact, creators experience a variety of emotions during the creative process. Surprise, satisfaction, enjoyment, and happiness are some of the feelings experienced by an artist when coming up with a creative idea or seeing the reactions of people for their creative products.

Beyond being the result of creative ideas and expression, surprise itself may foster creativity. In a recent study, Malgorzata Godowska et al. (2014) examined the influence of surprise on creativity. More specifically, they proposed the concept of the “need for structure”, positing that some people may prefer a structured world and following explicit and well-defined rules, whereas others might be more flexible and tolerant of ambiguity and unexpected events. A series of pictures was presented to the participants, who were asked to study them for a following memory test. The pictures were in two different formats, with consistent vs. inconsistent content, such as an Eskimo on a desert, an astronaut on a beach, or a football player on an ice rink for inconsistent examples. Then, the participants were asked to complete a divergent thinking test that asked them to create new names for a pasta. In a second study, the same procedure was repeated with a different series of pictures, and the participants were asked to complete a Remote Association Test (RAT). Presenting consistent pictures did not make any difference in the participants’ creative performance. For the group with inconsistent pictures, however, the participants with a low “need for structure” were remarkably more fluent in their responses and similarly performed better on the RAT. The results suggested that when individuals who are flexible and tolerant to ambiguity are exposed to surprising concepts, they are more likely to think in a divergent way.

Novelty and Surprise

Creativity comes with surprise, and novelty and surprise are highly related concepts. Although there is some disagreement among researchers about the definition of creativity, novelty has been cited as one of the defining characteristics of creativity. It refers to any kind of creative response that deviates from the conventional and expected one. Novelty may be manifested in a range from slight deviation to a breakthrough in science or the arts. Although the term “unexpected novelty” has been used in creativity literature to refer to surprise, they differ slightly. Novelty refers to the degree a creative work is new or different from an existing one in a particular domain. Surprise, on the other hand, is more about the violation of expectations; thus, it is more personal and subjective.

Surprise also differs from novelty in regard to its underlying mechanism. Surprise is a temporal process that relies on cognitive schemas and memory. Schemas are the building blocks of our memory, and any violation of existing schemas or expected output in a given situation leads to surprise. Novelty, however, is relatively independent from personal expectations. Novel ideas or products lead to surprise in most cases, but the opposite is not true for many situations. The novelty in Picasso’s cubist art or the architectural design of Utzon’s Sydney Opera House is surprising for many people, whereas a “surprise birthday” party in the classic sense of a cake, candles, and prizes, while perhaps surprising for the birthday boy/girl, is highly questionable as a creative act. From a different perspective, flying cars have been expected for a long time, but despite being an expected invention, such machines are still highly novel.

Creativity and Different Types of Surprise

Surprise can take many forms depending on the form of creativity manifested. For instance, Boden (2004) defined three types of surprise. First, people may be surprised by a new idea, product, or situation that is statistically unusual and contrary to common expectations, such as a high school student earning a college degree upon high school graduation. Second, surprise occurs when people have not seen an idea as a possibility. A human being setting foot on the moon was just a fantasy for

a long time and was highly surprising when finally achieved in 1969. Lastly, people are surprised by an idea that has been considered as impossible and still seen as counterintuitive, such as wireless chargers, augmented reality, or motion-controlled electronic systems.

Corresponding to these three kinds of surprise, Boden (2004) also identified three types of creativity. Combinational creativity, for instance, arises from the unusual combination of relatively known ideas and is associated with the first type of surprise covering statistically unusual ideas. Visual collages, different types of analogies, and unexpected juxtapositions of ideas found in political cartoons are some of the everyday examples of combinational creativity that lead to surprise. Similarly, exploratory creativity uses available knowledge to generate novel ideas, but instead of just combining two known ideas, it goes beyond existing structures and displays new and valuable possibilities, which may lead to even greater surprise and excitement. Exploratory creativity does not have to be a matter of adopting something without thinking. It may include thoughtful exploration and the testing of specific stylistic boundaries, which explains why exploratory creativity plays a central role in the lives of artists and scientists. Boden further pointed out that exploratory creativity usually comes with surprise. It is not only because people are surprised when discovering a new idea but also the fact that how this profound idea was previously unseen.

Lastly, transformational creativity is the type that generates the highest surprise, amazement, and incomprehension. It refers to changing the rules or the conceptual space, allowing for the generation of something new that was previously impossible. Exploratory creativity is often associated with ordinary research processes that seek solutions for everyday problems, whereas transformational creativity is seen as those major breakthroughs that redefine our perception, experience, and understanding of problems, research fields, or the arts. Picasso's cubist style and the canvas of *Les Femmes d'Alger* was a transformational landmark. It is not surprising that creative products emerging through transformational creativity lead to personal experiences like seeing the unseen or experiencing the unexperienced.

Similarly, Bruner (1962) presented three types of effective surprise as predictive, formal, and metaphorical effectiveness. Predictive effectiveness refers to surprises arising through relatively predicted events, such as reformulation or reconceptualization, a known phenomenon in science. Formal effectiveness occurs when one sees a connection or relationship never found before or re-organizing things in an unusual way. Finally, metaphorical effectiveness refers to the combination of seemingly unrelated things such that these connections form art. In general, it is the experience that combines known things in an unexpected but effective way and surprises the audience.

Definition of Creativity and Surprise

Although there is no universal definition of creativity, originality and effectiveness are commonly considered defining characteristics of creativity. Originality refers to novelty, being new, unusual, and unique. Since it is not concerned with usefulness or effectiveness, originality is necessary but not sufficient in itself to define creativity. For instance, using a shoe as a saucepan may sound highly original, but it is neither useful nor effective for cooking purpose; thus it should be not be considered as creative. Beyond being original, creative ideas and products should be effective, serving a specific purpose or fitting a given problem condition. While a variety of relevant terms, such as usefulness, value, and appropriateness, have been cited in the literature for this second criterion, a two dimensional approach – originality and effectiveness – is commonly used for the definition and assessment of creativity.

The two-criterion view has been embraced by many researchers and practitioners; however, there has been an effort to extend the common two-criterion view to a three-criterion approach. The new approach provides a viable way to understand creativity and differentiates the creative process from other cognitive processes that lead to ordinary improvements. In his seminal 1962 paper, "The Conditions for Creativity", Jerome Bruner defined creativity as "*an act that produces effective surprise*". His approach suggests that regardless of the domains or different forms that creativity manifested itself, the creative process should end up with an effective surprise. Beyond the classic view of surprise and unexpectedness, Bruner pointed out that effective surprise requires that a creative product should be related to one's interests, personal life or experiences. Thus, people may not react to novelty with which they feel no connection. More recently, Boden also included surprise in her definition of creativity that creativity is an ability to come up with an idea or product that is new, valuable, and surprising.

Interestingly, surprise is considered an essential criterion of creative production in patent applications. Based on the US Patent and Trademark Office's description, an invention should be novel, useful, and nonobvious, which could be translated as surprise, in order to be granted patent rights. A patent application might be rejected "*if the differences between the claimed invention and the prior art are such that the claimed invention as a whole would have been obvious before the effective filing date of the claimed invention to a person having ordinary skill in the art to which the claimed invention pertains.*" A person with ordinary skills could be considered as someone with domain-specific expertise. If a new invention can be re-created by a person of ordinary skill, it indicates that the new invention is but a predictable or expected variation of the present version. For instance, imagine that a patent is granted for ice cream waffle cones; then, a new patent application is submitted for a waffle cone used for a different food, such as salad or fruit. For evaluation purposes, using waffles cones with different foods is an obvious and predictable improvement; thus, overall, it is not considered creative and should receive rejection for a patent application.

Based on US Patent Office's criteria of creativity, Dean Keith Simonton (2012) proposed a new definition of creativity with three criteria: novelty, utility, and surprise. Simonton argued that including surprise as a new criterion leads to four implications for creativity: limitations based on domain-specific expertise, varieties of comparable creativities, subjective versus objective

evaluation, and lastly, blind variation and selective retention in the creative process. More specifically, since the person with domain expertise plays an important role in evaluation of surprise, the three-criterion definition leads to limitations determining creative products that are highly sophisticated and interdisciplinary. Secondly, the new definition allows greater variance and flexibility in the assessment of creativity. Third, the new definition provides both subjective and objective aspects in the evaluation of creativity that includes creators' subjective experiences and evaluators' objective expertise and assessment. Finally, extending two-criterion definition with surprise supports the idea that blind variation and selective retention play an essential role in the creative process.

Although surprise as a separate dimension of creativity was introduced by Bruner in 1962, today it is still regarded as a novelty-related term by many researchers. The aforementioned novelty-surprise distinction may need further theoretical and empirical studies to recognize surprise as a distinct defining characteristic of creativity. Nevertheless, including surprise in definition of creativity can certainly contribute to understanding, assessment, and application of creativity in a broader sense. Obviously, surprise is a fundamental characteristic of novel products and an emotional reaction to creative production, thus, to some degree, any definition of creativity should give weight to the idea of surprise as a defining characteristic of creativity.

Eureka, Aha Moments, and Insight A eureka moment, called "aha" experience, and insight are related concepts that lead to surprise. The Merriam-Webster Dictionary defines the eureka or aha moment as "*a moment of sudden realization, inspiration, insight, recognition, or comprehension.*" It is the moment when the brain figures out the solution for a problem that it has been dealing for a while. It is an unconscious process called as incubation that occurs from the culmination of previous work. It is one of the stages proposed by Graham Wallas (1926) in his theory of the creative process. Wallas explained the creative process in four stages as preparation, incubation, illumination, and verification. Preparation is the stage of identifying a problem and gathering information about it. Incubation is the stage when people come up with creative ideas and solutions after taking a break from struggling with a problem. What happens in our brains or where those eureka moments come from is still a mystery to some degree. One explanation is that incubation allows the mind to wander and temporary changes the focus of attention from the problem, thereby cultivating opportunities for creative insights. Neuroscience reveals that different parts of the brain are activated during insight experiences. For instance, people who use insight for problem solving exhibit greater right parietal activity, associated with high attention and less control. By contrast, people who use analytical thinking experience higher left frontal activity that fosters more control and organization of thoughts. Regardless of the source of insight, many studies in the literature indicate that incubation is commonly experienced by many people in a variety of fields. It is surprising that some of the most influential ideas have arisen through creative insights. The eureka moment Sir Isaac Newton experienced is maybe the most famous. He saw an apple falls from a tree and became fascinated with the idea that all apples fall perpendicularly toward the earth. This experience led him to discover the law of gravity. Similarly, Archimedes discovered the Archimedes Principle while taking a bath. He was so excited and even rushed home naked, yelling, "Eureka! Eureka!" meaning "I've found it! I've found it!" in Greek. The invention of penicillin, the microwave, popsicles, Play-Doh, and many other discoveries have similar stories. Moreover, insights and eureka moments are not limited to scientists or artists that many people experience creative insights and aha moments in their daily lives at some level and feel surprised when a creative solution pops up in their minds.

Violation of Expectation The violation of expectation is the underlying mechanism of surprise such that any unexpected behavior or stimuli leads to the emotion of surprise for observers. Expectations are part of the learning process in children's development. Children are full of surprise and highly creative in their behaviors, expressions, and art forms during childhood. However, they gradually become more aware of conventional norms, appropriate behaviors, and expectations, which in turn lead to losing creativity as they grow up. The fourth grade slump, referring to the significant decline in children's creativity at this time, is a well-known phenomenon indicating that children lose their creativity as they become developmentally and cognitively mature and more concerned with expectations.

Frank Lachmann (2006) proposed that creativity and perversion are based on the violation of expectations. He stated that the violation of expectations is a motivational factor for creativity, and such violations lead to surprise and shock for observers. In his study, Lachmann elaborated on Marc Chagall and Richard Wagner and how violation of expectations played an important role in their creativity. Both artists were physically weak at birth, and their parents did not expect them to survive. They first violated expectations through their physical development: later, Chagall in his paintings and Wagner in the realm of opera designed their arts in such a way as to violate common designs and expectations. They were considered as the contrarians of their time. Contrarian people think in a way that significantly differs from the mainstream, thus violating expectations and causing surprise in other people. In an experimental design, Ritter et al. (2014) investigated the role of the violation of expectations, called schema violations, in fostering cognitive flexibility, an essential mental ability in creative thinking. In a 2×2 group design, they presented a video showing the preparation of a sandwich in a regular way, while for the second group, the chef followed a completely odd sequence in its preparation. For the second group, some of the participants were also asked to imagine themselves as the chef in the video. In a second study, a similar research design was repeated and the participants' brain activity was observed with functional Magnetic Resonance Imaging (fMRI). The results of the study indicated that those who assumed the role of the chef in the violated scheme shown in the video showed greater cognitive flexibility and brain activity in their temporal parietal junction (TPJ). This implies that without any physical involvement, cognitive flexibility may be improved through exposure to a stimulus that violates personal expectations. It should be noted that most creative ideas and productions are subject to violation of expectation, but not all violations of expectations or cases of contrarianism lead to creativity. Some people can go against the crowd just to be able to attract attention or build an identity or self-image around contrarianism. These could well be signs of creativity, but it is not necessarily true that all weird behaviors or expression should be considered as creative acts.

Adapters Versus Innovators

Clearly, the creative process and products are highly related to surprise, but a creative person is also an important factor in understanding creativity and the creativity-surprise connection. It is a common experience to have friends full of surprise and others who behave relatively in an expected way, thus not surprising. The question is what makes someone more likely to surprise others or lead to amazement? Michael Kirton's (1976) Adaption-Innovation Theory provides a framework to understand the relationship between different styles of creativity, creative persons, and surprise. Kirton's theory described two different creativity styles, namely, adaption and innovation, or adaptors and innovators in a personal context. While adaptors focus on innovation and "doing things differently," adaptors are more concerned about improvements or "doing things better." They differ in their personal characteristics in that innovators are considered to be associated with extraversion, risk-taking, flexibility, tolerance to ambiguity, a lower need of structure, and openness to experience. Kirton himself described innovators as seemingly undisciplined, having unusual perspectives on tasks, capable of a detailed task in a short time, seeking extraordinary change, and showing high self-efficacy in idea generation. Adaptors, on the other hand, are more likely to follow conventional thinking, be more comfortable with the status quo, and needing a more structured environment and working procedure. In Kirton's description, adaptors are more concerned with problem solving rather than problem finding. They use an existing framework and structure to solve problems, show a high performance in detailed tasks, rarely challenge the status quo, and care more about others or group harmony. The characteristic differences between innovators and adaptors do not necessarily indicate the latter are not creative. Instead, the theory suggests that adaptors prefer different manifestation of creativity within a given framework, while innovators are more open to new possibilities. Based on these descriptions, it should not be surprising that adaptors are more likely to generate combinational or predictive creativity and innovators to produce transformational and metaphorical creativity as discussed above. It may be expected that innovators will lead to greater surprise in their career professions and possibly in their personal life and relationships. Since adaptors are less likely to challenge group rules or conventions, they may not display unexpected behaviors and surprise other people, both in their work and personal lives.

Conclusion

Surprise is an emotional reaction to unexpected stimuli, and several conclusions may be drawn regarding the creativity-surprise connection. Some parts of the brain associated with creativity are more activate during the experience of surprise. Next, surprise is inherently experienced when someone encounters a novel idea, production, or creative insight; thus, it is an essential part of the creative process. Additionally, there is a growing body of literature suggesting that surprise is a defining characteristic of creativity and should be involved in the definition of creativity as a third criterion. Finally, promising research efforts now show that beyond being the result of the creative process, surprise, more specifically the violation of expectations, can boost creative expression and production.

Arriving at a more complete understanding of creativity requires that it be studied at multiple levels of analysis. Over the 60-plus years since it was charted as a research domain, creativity scholarship has largely centered on examining the psychological attributes and processes within the individual. Since the mid-1980s, however, systems approaches have emerged as important lenses for understanding creativity as situated within broader contexts. All systems approaches share theoretical principles and, to some extent, vocabulary and foundational bases for research methodologies. As characterized by Kozbelt et al. (2010), "Some of the broadest and most ambitious theories of creativity take the view that creativity is best conceptualized not as a single entity, but as emerging from a complex system with interacting subcomponents—all which must be taken into account for a rich, meaningful, and valid understanding of creativity" (p. 38).

Systems Thinking

Bunge, whom Pickel (2011) describes as one of the most eloquent and incisive advocates for the systems philosophy, describes a system as "a complex object [entity] whose parts or components are held together by a bond of some kind. These bonds are logical in the case of a conceptual system, such as a theory; they are material in the case of a concrete system, such as an atom, cell, immune system, family, or hospital. The collection of all such relations among a system's constituents is its structure (or organization, or architecture)" (Bunge, 2004, p. 188). While conceiving the universe as comprised of systems is not original to the 20th and 21st centuries, the concept gained significant traction in the mid-20th century. Ludwig von Bertalanffy proposed, expanded, and revised his theory over several decades, culminating in his capstone work *General System Theory: Foundations, Development, Applications* (1968). His title's use of the singular "system" theory, instead of the much more prevalent "systems," conveys his formidable quest for one unified theory that would transcend all disciplines. By the time of his volume's publication, however, his view no longer held currency among scientists. His attempt to "transcend analytical philosophy of science" was not successful and his goal seemed well beyond the reach of the social sciences. The theory was deemed too vague, unwieldy, and not testable.

We cannot, however, diminish the influence of such early forerunners on contemporary systems approaches. Early systems thinking codified a vocabulary and concepts that are now part of our cultural consciousness. The idea of a system as components held together by a bond is now conventional wisdom. We do not see as alien the central tenet of "holism" (that a phenomenon is not due to any single cause, but to a network of interacting parts). The idea that "open systems" interact with their environments and that "closed systems" do not is also now understood intuitively. Many of the sciences share a grammar in the analysis and discussion of life represented by such terms as "equifinality" (that the same goal can be achieved through different paths); "isomorphism" (that structural, behavioral, and developmental features and laws are shared across systems); and "emergence" (that novel properties arise as evolving organisms seek higher levels of complexity). "Positive feedback," "negative feedback," and "feedback loops" are now terms fundamental to the biological, physical, and social sciences.

New Systems Thinking

Following a largely fallow period that began in the late 1960s, systems theories, for the last 30 years, have been experiencing a renaissance. Pickel (2011) refers to this collection of approaches as “new systems.” Bunge (2004) uses the terms “systemism” and “systemic approach” to represent such contemporary approaches as, but not limited to, nonlinear dynamical systems theory (i.e., chaos theory), dynamic systems theory, autopoietic (self-organizing) systems theory, and complexity theory. Although robust progeny of the systems thinking of the 20th century, these newer theories share core principles significantly reformulated from General Systems Theory (Pickel, 2011). Newer systems approaches are not a vague kind of holism (Poutanen, 2013), a common criticism of the Bertalanffian view. These new approaches emphasize analysis as much as synthesis. Central to these theories is the principle of emergence, the process by which novel properties arise—when components of lower complexity are combined in novel ways.

Unlike their predecessors, the newer approaches recognize the necessity of describing the mechanisms underlying a system. The processes might not follow linear, causal laws; they can be nonlinear and cyclic, arising from the interconnected nature of the system and multiple feedback loops (Montuori, 2011), but a mechanism-based explanation is essential for a theory to have an ontology and methodology that is taken seriously (Bunge, 2004). Of the new systems approaches, Poutanen (2013) contends that complexity theory, in particular, may have the strongest power to illuminate general mechanisms. These newer approaches have been applied in linguistics, cultural studies, psychology, economics, ecology, neuroscience, sociology, history, organization studies, political economy, global studies, engineering, sociology, computer science, mathematics, ecology, human development, art, the humanities, and education.

Systems Approaches to Creativity Research

While General Systems Theory failed to meet its ambitious goal of providing a unified, transdisciplinary theory, it did create a seedbed for scholars to think in terms of systems—including in application to creativity. The first two waves of creativity research focused on the individual: the personality psychology approach in the 1950s and 1960s and the cognitive psychology approach, which began in the 1970s and continues to the present. With Amabile's *The Social Psychology of Creativity* (1983) and her subsequent *Creativity in Context* (1996), the argument for a sociocultural approach was established. Amabile posited that creativity happens within contexts, within environments that have significant influence on both the creative process and the creative product. Simon-ton, as well, was early on the scene, offering vast collections of data and comprehensive explanations of the larger environment's role in shaping creativity (Simonton, 2014).

In the study of creativity since the mid-1980s, many systems approaches have emerged. Following is a brief, noncomprehensive discussion of several. Some do not use the term “systems,” but nonetheless implicitly share systems principles. Because of its impact and prominence, Csikszentmihalyi's Systems Model of Creativity (Csikszentmihalyi, 1988), also referred to as the DFI Model, will be discussed in detail.

Csikszentmihalyi's Systems Model of Creativity

By the mid-1980s, Mihaly Csikszentmihalyi had been engaged in the serious study of creativity for over 20 years, dating back to his dissertation research studying the creative processes of young artists. As a new scholar, he assumed, as was the custom among those studying creativity during those early years, that creativity consisted of the traits/abilities/talents/skills that resided within the person.

As Csikszentmihalyi has reported (1988; 2014a), he became less certain of the widely shared assumption about the locus of creativity. His skepticism was sparked when contemplating results of the longitudinal study of artists conducted with his PhD advisor, Jacob Getzels, in which they had discovered evidence that the creative ability (perceived by expert judges) of young artists was not a predictor of those artists' success years down the road. In fact, following the artists over time, they observed that the larger sociocultural environment, especially in the cases of female and black artists, had a significant bearing on later success. And, adding to their surprise, many of those deemed less creative when younger were more successful in their later contributions as artists because of the opportunities and resources afforded by their environments. Neither talent, nor cognitive, emotional, and motivational processes appeared to be the most influential factors in participants' artistic achievement.

Looking for creativity in the psyche of the individual could never lead to a full understanding of the phenomenon because the individual was only part of a larger phenomenon. Unveiled in 1988, Csikszentmihalyi's Systems Model of Creativity is the dominant explanation for how creative contributions make an impact upon a domain and change the culture. Applying the distinction usually attributed to Stein, this model intends only to explain Big C, eminently creative accomplishments, rather than small c, everyday creativity. Big C creativity propels the culture and our species forward. It is a level of creativity that is rare, that produces a consequential impact, and that, as a result of some form of adjudication, is socially valued, certifying that the novel idea or product is better or more useful than its predecessor. The Systems Model (see Fig. 1) illustrates that creativity is not a set of individual attributes, but that creativity, and ultimately creative contributions, happens within a larger sociocultural system of which the person is an important component, but not the only one.

Figure 1 Systems Model of Creativity.

The Domain

All societies produce a culture, the system of learned rules that regulate to various degrees its people's thoughts, beliefs, and behavior. Culture organizes those rules into domains. Mathematics, education, government, transportation, childcare, and art are but an infinitesimal sampling of the thousands of explicitly organized domains in our culture. Domains, furthermore, are comprised of subdomains: number theory is a subdomain of mathematics, evolutionary biology a subdomain of biological science, and animation a subdomain of art. Over time, each domain and subdomain have developed boundaries and rules that define which processes, norms, procedures, and beliefs are appropriate. By nature, many domains are self-protective, conservative, determined to protect their very existence. They evolve slowly, sometimes only reluctantly, if ever, welcoming new ideas and innovations. Some domains, however, are much more relaxed, freely admitting new ideas and change.

For 300 years, the domain of science was fiercely protective of the Cartesian and Newtonian paradigms. Those perspectives on the universe and the companion method for conducting science were not open to change because the domain was convinced that these paradigms described the Truth. However, in part due to systems thinking and new conceptions of physics, the domain of the physical sciences did ultimately evolve, and quite rapidly, in the face of new, undeniable evidence about the Universe.

The Person

Most people find acceptable the rules, procedures, and norms that domains and subdomains have transmitted through their formal and informal education and through life experience. They will follow the conventions they're expected to without questioning their assumptions. Most, for example, won't ponder whether or not the conventional explanation of Time is correct. Some, however, because of genetics, personality, motivation, and factors not yet understood or even identified, will come to believe they can improve an existing domain. Doing so, however, almost always requires that the Person have expertise. Those wanting to make creative contributions usually find that there are far more persons like them with novel ideas and innovations than the culture can possibly pay attention to. The number of artists, actors, and authors far exceeds the number of galleries, roles, and publishers available to advance them. Relatively few persons successfully change a domain—even fewer gain the momentum of additional contributions and build a canon of creative work.

The scientific revolution of the early 20th century happened, in part, because pioneers such as physicists Werner Heisenberg, Albert Einstein, and Niels Bohr were instrumental in the development of quantum physics. The talent, curiosity, personality traits, and cognitive abilities of these Persons prohibited them from accepting the Domain of physics as it existed.

The Field

How do ideas and innovations make their way from the Person to a Domain? Most ideas will not improve the Domain and some will likely make things worse. It is the role of the Field, which sometimes consists of society more broadly, to screen potentially creative contributions to a Domain. "Field" as used here does not refer to a discipline or area of expertise, which is more closely related to the concept represented by the term "Domain." Consistent with the perspective of most creativity scholars, the Systems Model presumes that a product's creativity requires adjudication. It must be seen as having value by the Field, the gatekeepers to the Domain. Within the world of fine art, the Field in part is comprised of critics, gallery owners, and collectors. In the sciences, major creative contributions occur because the gatekeepers (journal reviewers, academic peers with sophisticated expertise, foundations that provide research funding) validate new ways of thinking and engaging in science. Csikszentmihalyi (2014a) argues, "If all it takes to be creative is for a person to believe in their own creativity, then everybody is creative, and the term is synonymous for 'human being'" (p. 540). Novices are unlikely to produce the kind of novelty that will be reviewed favorably by gatekeepers.

The Systems Model is not without limitations and criticism. Kozbelt et al. (2010) are generally positive in their assessment, citing its importance for bringing attention to sociocultural influences on creativity. The model's application over multiple levels of

analysis can create methodological challenges, but they acknowledge that this seems an acceptable tradeoff. Their most serious concern is that the model's qualitative nature "may make it more difficult to test hypotheses unambiguously" (p. 40). Weisberg is more critical, taking issue with Csikszentmihalyi's insistence that a product's social acceptance is necessary for it to be deemed creative. Instead, Runco et al. (2010) take exception to a related issue: the model's assumption (intellectually consistent with the rest of the model) that an individual's creativity can change over time (Csikszentmihalyi, 2014a). The model is used to support the argument that if the culture and a Domain are hospitable to the Person's idea or product, he or she is considered creative. However, if the Person's contribution is no longer supported by the Domain after death, in keeping with the Model, the Person would no longer be considered creative.

Applications of the Systems Model

The Systems Model has influenced a significant body of theoretical and empirical scholarship represented by the following synopses.

Nakamura and Csikszentmihalyi (2003; reprinted in Csikszentmihalyi, 2014b) offered the Systems Model as a lens for viewing creativity in the lives of eminently creative persons whose achievements had traditionally been explained through conventional, deficit-based models. The authors integrated Bloand's deficit-based analysis of her father Erik Erikson's pursuit of fame with a strengths perspective. They apply the Model as a framework to explain Erikson's investment of attention in his creative achievements as a psychologist. Csikszentmihalyi and Nakamura (2006; reprinted in Csikszentmihalyi, 2014b) have also employed the Systems Model in an argument for viewing human aging from an evolutionary perspective. The exploratory behavior that undergirds creativity into the last years of life, they argue and support with exemplars, is contingent upon the Domain of the person's work, as well as the opportunities and obstacles of the Field, both critical for sustaining curiosity, interest, and passion. The Systems Model can serve as a framework for positive aging, as well as a tool for researchers seeking to explain the role of aging in the lives of study participants.

Perhaps a natural extension of the model is its application beyond explaining individual creativity, to providing a framework and vocabulary that organizations can apply to create environments that are high-functioning and innovative. Csikszentmihalyi and Sawyer (1995; reprinted in Csikszentmihalyi, 2014b) make the case that organizations desiring to increase creativity and innovation should cease their inordinate focus on individual creativity and, instead, focus on using the Systems Model as a basis for developing organizational creativity. Csikszentmihalyi and Wolfe (2000; reprinted in Csikszentmihalyi, 2014b), in "New Conceptions and Research Approaches to Creativity: Implication of a Systems Perspective for Creativity in Education," argue for the model's utility in developing learning environments that will result in increased creativity in schools.

Several publications by Csikszentmihalyi and collaborators report on studies for which the Systems Model has served as a theoretical foundation and, in some cases, has shaped study design, data collection, analysis, and interpretation. Drawing from interviews with eminently creative persons collected in the Creativity in Later Life Study (Csikszentmihalyi, 1996), Csikszentmihalyi and Sawyer (1995; reprinted in Csikszentmihalyi, 2014b) explore the relationship between an individual's insights and his or her facility for accessing the Field and contributing to a Domain. Drawing from the same dataset, Mockros and Csikszentmihalyi (2014; reprinted in Csikszentmihalyi, 2014b) examine the influence of Fields and Domains on historical, educational, professional, and cultural systems, particularly the ways culture contributes to the absence of creative women in specific domains. In "Catalytic Creativity: The Case of Linus Pauling," Csikszentmihalyi and Nakamura (2001; reprinted in Csikszentmihalyi, 2014b) marshal evidence for the significant role of the Field in mediating meaningful interactions between the Person and the Domain over a career. Integrating systems thinking and Bourdieu's concept of Social Capital, Hooker, Nakamura, and Csikszentmihalyi (2003; reprinted in Csikszentmihalyi, 2014b) report on a study of university student apprentices in a space science lab and make several recommendations for optimizing mentoring conditions. In their historical analysis of painters and painting, Abuhamdeh and Csikszentmihalyi (2014; reprinted in Csikszentmihalyi, 2014b) use the Systems Model to build a case for the personality of artists as dependent upon the characteristics of the Field and the Domain at the time they are alive and painting. Sawyer has devoted considerable attention to the work and lives of jazz musicians, arguing that the most successful ones develop a deep and intimate knowledge of the Domain and its relationship with the Field. Those musicians develop and carry an internal mental model of the Field and the Domain (Csikszentmihalyi and Sawyer 1995; reprinted in Csikszentmihalyi, 2014b).

Other Systems and Systems-like Approaches in the Study of Creativity

Additional systems approaches to studying creativity at varying levels of analysis have evolved since the mid-1980s. Many do not explicitly use the term "systems." They range from those that acknowledge the influence of proximal and distal environments upon creativity to those that, like the Systems Model, suggest that environment is an equal co-creator in the manifestation of creativity. For a general sense of these approaches and how they have evolved, following is a rough chronology. Most of the 10 approaches listed here have dedicated articles within the *Encyclopedia* and/or are discussed in other articles.

1. Gruber's Evolving Systems Approach (ESA) (see summary by [Stahl and Brower, 2011](#)) is a theory and method for studying creative individuals. While examining purpose, affect, and knowledge within the creative person, the theory and method were constructed to emphasize the ongoing environmental influence upon the creator.
2. Amabile's Componential Model of Creativity is an influential systems model that identifies the circumstances conducive to creativity as those at the intersection of Domain Skills, Intrinsic Motivation, and Creative Thinking and Working Skills.
3. Gardner's Symbol System Approach (SSA) proposes four levels of analysis—Biological, Psychological, Epistemological (The Domain), and Sociological (The Field)—in the development of extraordinary cognitive achievements.
4. Sternberg and Lubart's Investment Model of Creativity argues that creative persons need to pursue a new idea early in the idea's life cycle, sell the novel idea to the Field, and then back away, allowing others to sustain the idea. Central to this concept of buying low and selling high is the influence of environmental context.
5. Feldman identifies seven dimensions of creative development, most of which have a strong sociocultural influence, that permit individuals to develop extraordinary creativity in particular domains.
6. John-Steiner influenced by Vygotsky's theory on the central importance of interpersonal experiences in learning and cognitive development has developed a body of work supporting the crucial role of collaboration in the development of creative products.
7. Simonton's Evolutionary Model argues that individuals, through a variety of influences, including the zeitgeist or current social environment, generate a vast number of ideas and combinations of ideas.
8. Puccio and Cabra's Creative Change Model illustrates how person(s), process, environment, and product influence one another, leading to creative change within organizations.
9. Hennessey's Classroom Systems Model situates the skills and knowledge necessary for an individual's creativity within the "Little c" (classroom or workplace) culture and positions that within the "Big C" (geographical area, ethnic group, or nation) culture in order to illustrate the continuous influence of multiple levels of culture upon creativity.
10. Glăveanu, in what could prove to be groundbreaking systems model, has proposed a cultural framework of creativity that views creativity as a sociocultural-psychological process. Recasting culture more broadly than in the tightly defined definition central to the Systems Model, he argues that because creativity is both individual and sociocultural, both levels of analysis explain how creative persons engage in cultural participation. Glăveanu uses craft-making to illustrate that a strict view of domains excludes amateur craftspersons who are also engaging in cultural participation. This conception of systems holds promise as a possible resolution to the thesis–antithesis divide between the Individualist (small c) and the Socioculturalist (Big C) paradigms.

Newer Systems Approaches to Studying Creativity

Chaos Theory and Complexity Theory

Nonlinear dynamical systems theory (chaos theory) and complexity theory are two dominant derivatives of the older systems thinking of the 20th century. Both have been widely applied as theoretical frameworks in multiple disciplines, particularly in organizational science, innovation studies, engineering, computer science, and the social sciences. A few examples of how both have been applied in creativity research are provided.

Chaos theory, which is evolving rapidly from the field of mathematics, is a way to understand the flexibility, order, disorder, adaptability, complexity, and self-organization of systems. The dynamic component refers to the fact that these systems are temporally unstable; they change over time. The nonlinearity component, rather than referring to the traditional relationship between an independent and a dependent variable, signifies the randomness of the internal components of the system. It is a tenet of chaos theory that an underlying order or pattern can, with sufficient exploration and testing, be identified under the apparent disorder of the system.

Complexity theory is not one theory, but a mathematically based science of exploratory research into self-organizing, emergent behavior within complex systems ([Poutanen, 2013](#)). It explores how order emerges from the interaction within a system and reflects a hope for eventually identifying transdisciplinary principles of emergence.

Following many years of research into optimal experience (flow), Csikszentmihalyi proposed that the order underlying all complex systems can be represented by the complementary processes of differentiation and integration, a mechanism that accounts for the development of all living systems "from the simplest amoeba to the most sophisticated human creature" ([Csikszentmihalyi, 1996](#), p. 362). All complex systems seek differentiation (movement toward uniqueness and change by taking on new parts and functions) and concurrently seek integration (working to maintain continuity and stability). Csikszentmihalyi argues that complexity underlies all systems including, but certainly not limited to, schools, organizations, neighborhoods, families, cities, cultures, and individuals. Some entities are more highly optimized due to higher levels of, and a better balance between, differentiation and integration.

Following Csikszentmihalyi's earlier work applying methodologies to explain complexity within schools and families, [Gute et al. \(2008\)](#) applied the framework to study creativity. The project explored complexity, as measured by the four combinations of high and low levels of differentiation and integration, in the early family lives of nine eminently creative persons: Wayne Booth, John Hope Franklin, Oscar Peterson, Ellen Lanyon, Nina Holton, Hazel Henderson, Freeman Dyson, Robertson Davies, and an anonymous psychologist. All were among the 91 participants of the Creativity in Later Life Study ([Csikszentmihalyi, 1996](#)). Consistent

with chaos theory's supposition that an order underlies the apparent disorder of all living systems, participants' coded recollections identified significant evidence of the interplay between integration and differentiation, which served as a catalyst for the optimal experience (flow) common to exemplars who have made meaningful changes to domains.

The self as a complex system is developing as an important level of analysis for complexity theory. Csikszentmihalyi and Rathunde (1998) enumerated the theoretical underpinnings of psychological complexity and reported their findings on the ontogenesis of psychological complexity among highly creative exemplars, arguing that creative contributors to the culture, in part through ongoing interactions with their respective fields and domains, build a set of cognitive, social, emotional, and behavioral capabilities representing opposites. Their claim holds that it is the ongoing processes of differentiation and integration that allow them to build a constellation of opposite traits (i.e., their psychological complexity). The theory holds that highly creative individuals seek differentiation by exercising their agency, divergent thinking, playfulness, extroversion, energy, and iconoclasm. The theory holds that highly creative individuals seek differentiation by exercising traits such as agency, divergent thinking, playfulness, extroversion, energy, and iconoclasm. At the same time, creative persons seek integration by exercising opposite traits such as communion, convergent thinking, discipline, introversion, quietude, and tradition.

Gute et al. (2016), in an investigation to further explore the mechanism—identified by Bunge (2004) as critical for an effective systems approach—by which eminent achievers build their repertoire of cognitive, social, and emotional opposites, undertook a thorough analysis of evidence of both extraversion and introversion within the experience of jazz pianist and composer Oscar Peterson (interview transcript from the Creativity in Later Life Study, Csikszentmihalyi, 1996). They found significant evidence that Peterson intentionally and consistently developed his introversion (i.e., building his integration) as a counterbalance to his naturally strong extraversion. The result was that, over time, Peterson experienced emergence a new ambidexterity that served him in his efforts to influence the field and contribute to meaningful domain changes as both a composer and performer. The identification of this mechanism, which McAdams (2005) has separately identified as making characteristic adaptations, brings us closer to accounting for the process of emergence in highly creative persons.

Poutanen (2013) provides an important caveat for applying complexity theory within the social sciences, where complexity concepts are still largely metaphorical. The fundamentals of complexity science are in mathematics. While we are a long way from employing the mathematics of complexity to measure the quality of emergence within the person or a sociocultural system, advances in computational creativity may yield the development of algorithms that can expand complexity theory and explain creativity beyond metaphor and theory.

Conclusion

Systems approaches to creativity have been increasing in number and growing in influence for roughly the second-half of creativity's life as a research arena. There might now be reason to believe that the fracture between those studying creativity on the sociocultural level and those investigating it on the individual level can begin to heal. Approaches such as Glăveanu's sociocultural-psychological model can certainly help point the way. Moreover, chaos theory and complexity theory, while still young approaches, offer new tools for exploring and measuring the dynamics within systems at all levels of analysis. Bunge characterized how newer systems approaches can move us in the right direction (2003): "Individualism sees the trees but misses the forest, whereas holism sees the forest but overlooks the trees" (p. 75). He goes on to say that only newer systems approaches, such as, but not limited to, chaos theory and complexity theory, will allow us to see "the trees (and their components) and the forest (and its larger environment)" (p. 75) in their full complexity.

Glossary

Accommodation One kind of tactic, used when the individual him- or herself changes. New information might be obtained, expanding the individual's knowledge base, or the creator's perspective on the problem or topic might change.

Assimilation A second kind of tactic, used when the individual changes the problem or representation of the problem.

Metacognition Thinking about thinking; the recognition that individuals can control their own thinking.

Overjustification Occurs when the person changes his or her opinion such that some activity that was initially intrinsically motivated becomes extrinsically controlled.

Procedural knowledge 'Know-how,' information about how to get something done. It is distinct from declarative, conceptual, and factual information. Tactics are the actions prescribed by procedural knowledge.

Social loafing One explanation for the superiority of working alone over brainstorming. It occurs when people assume that someone else in the group will complete the task at hand.

Introduction

There are a number of things that can be done if a person wishes to increase the creativity of his or her own thinking and behavior. Tactics are particularly useful in this regard. They may be defined as consciously-used methods for increasing originality and ideation. Tactics also require an interest in being creative. They are intentional, and the individual will not expend the effort unless he or she is interested in being creative. They do require a certain level of maturity. That is because metacognitive; they require the recognition that we can control our own thinking, and this is not apparent until early in adolescence. They are also metacognitive in the sense that they are not dependent on basic (effortless) cognitive processes. This provides some optimism; it means that everyone, at all levels of ability, can probably enhance his or her creativity if the right tactics are identified and intentionally employed.

Procedural *knowledge* is necessary for tactical behavior. Procedural knowledge is 'know-how.' It is information about *how* to get something done. It is distinct from declarative, conceptual, and factual information. It might be most accurate to say that tactics are the actions prescribed by procedural knowledge. The tie to knowledge does raise the possibility that intelligence is involved. After all, intelligence is related to how well individuals learn and remember information. Still, the tie to intentions and the interest in being creative, which means original rather than conventional, suggests some separation of tactics from general intelligence. In sum, tactics are *relatively* distinct from traditional intelligence and general ability. Certainly creative thinking depends on both declarative and procedural knowledge, not one or the other.

Along the same lines tactics do not work in isolation. Attitudes are, for example, related to tactics. One relevant attitude concerns the belief that one is capable of creative thinking. The individual must also be interested in creative ideas; he or she must be willing to take

[☆]*Change History:* July 2017: M.A. Runco updated the text in this article. August 2019: His affiliation changed. Updates include clarification of how tactics are metacognitive and how tactics may be classified and used.

This article is an update of M.A. Runco, Tactics and Strategies for Creativity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 423–426.

risks and try something new. A creative attitude will insure that the individual approaches problems and tasks, if not life itself, assuming that it is possible and valuable to be creative. That individual is likely to learn and employ tactics for creative thinking. This is especially important because tactics can be learned, and attitudes are easy to change. Unlike personality traits, which represent stable tendencies, attitudes are relatively malleable. These ideas about the possibility of changing attitudes (e.g., so the value of creative ideas is foremost in one's thinking) and learning tactics have clear implications for efforts to enhance creativity.

Classifying Tactics

Tactics for creativity and originality have been classified in several different ways. These classification schemes are reviewed here. It is helpful to know which tactics are related to, and perhaps complement, other tactics.

One useful distinction between the different kinds of tactics was presented by Sidney Parnes. He referred to *let-it-happen* tactics and *make-it-happen* tactics. Incubation is an example of the former. Incubation cannot be forced, but it can be made more likely by taking a break from one's work, and perhaps by taking a walk or finding some optimally distracting activity. As a matter of fact research at Stanford University pointed specifically to taking walks as a means of letting creativity happen. Let-it-happen tactics also include (a) being open to change and serendipity and (b) trusting your intuition and hunches. In these cases, the individual is not directing the process but instead allows it to occur and simply appreciates the results. Individuals may go as far as to put themselves in a position where incubation, serendipity, and the like are highly likely to happen. It may be that all tactics allow information processing that is below the level of consciousness, with at least part of the benefit is beyond control. In a sense let-it-happen tactics may involve letting natural (e.g., intuitive) processing take place.

Make-it-happen tactics are more numerous in the creativity literature. Unlike let-it-happen tactics, make-it-happen tactics are usually more detailed step-by-step procedures. "Be a contrarian: Think of things no one else will," is an example of a make-it-happen tactic. For obvious reasons most of the efforts within schools, organizations, or training programs will involve make-it-happen tactics, simply because they are intentionally and systematically guiding creative thinking. The best of the programs probably also inform participants about let-it-happen tactics, and there are ways to demonstrate the benefits, even in a semi-controlled setting, such as a classroom.

A second way to distinguish among tactics involves stages of the creative thinking process. Certain tactics may be used within one particular phase or stage of the creative process. There are different stage models of the process but most follow from the theory presented by Graham Wallas in 1926, with preparation, incubation, illumination, and verification stages. Let-it-happen tactics are well suited to incubation, for example, just as tactics to 'seek out reliable information' and 'change perspectives' are well suited to the preparation stage.

Each of the four stages can be divided into two subcategories. For preparation, illumination, and verification this division reflects a separation between the subjective and the objective, or between the individual and everything else—the problem, the relevant information, the possible or tentative solutions, the setting, and so on. This subdivision follows from cognitive theories which divide information processing into assimilation (whereby information is changed to fit into an individual's existing personal cognitive structures) and accommodation (whereby the personal conceptual structures are changed to take advantage of the new information). (This subdivision for incubation may not reflect subject and object, but incubation is largely personal and subjective.)

Assimilatory strategies are those with which the creator changes the problem or representation of the problem. He or she might *turn the problem on its head*, for example, or *work backward* from the desired objective or solution to the initial state. Working backwards works especially well for scheduling and travel arrangements. Strategies using accommodation are those with which the creator him- or herself changes. New information might be obtained, for example, expanding the individual's knowledge base, or the creator's perspective on the problem or topic might change by investigating different points of view.

Changes of perspective represent what may be the most general kind of tactic. This is because such changes underlie a variety of more specific tactics. Turning a problem on its head, taking time away from the problem, traveling, *seeking out criticism* or input, and many other tactics rely on some sort of change in perspective.

Problem finding is a kind of preparation and can be easily related to both identifying and defining problems such that creative solutions are more likely. Many problem finding tactics involve information or other resources; just above I alluded to a 'seek out reliable information' tactic, which is a good example. 'Question assumptions' is another example of a tactic that applies well to problem finding. Like "change your perspective," questioning assumptions is a broadly-applicable tactic for creativity.

The tactic 'question assumptions' can also be worded 'do not make assumptions.' This rewording is only noteworthy because it highlights the last distinction that can be used to classify tactics. On the one hand there are tactics that suggest learning new behaviors. 'Seek out challenges' is an example of this kind of tactic. 'Do not make assumptions,' on the other hand, is an example of what can be called an *avoidance tactic*. This kind of tactic suggests what should be avoided, like assumptions, routines, and conformity.

James Adams' excellent volume, *Conceptual Blockbusting*, reviews many different kinds of avoidance tactics. What he suggests we avoid are conceptual blocks, which he then divides as follows:

- Perceptual blocks occur when we define a problem too closely or too generally, or we ignore important information or a useful perspective. We need to avoid preconceptions and stereotypes.
- Cultural blocks occur when we fail to utilize fantasy, play, daydreaming, and humor because, in our culture, they are not associated with serious work. Taboos can create blocks.
- Environmental blocks occur when we are distracted by our immediate environment, including people with whom we live or work.

- Emotional blocks occur when we are afraid of taking risks or are not comfortable tolerating the ambiguity that may be necessary while we incubate or think further about a problem. We may also be uncomfortable postponing a decision or solution or with challenges.
- Intellectual and expressive blocks occur when we are inflexible or do not consider alternative media for representing a problem. We might also fail to obtain the most useful information. We might find a solution but fail to record it.

Each of these ideas can be translated into a recommendation. The last idea, for example, concerning the recording of our ideas, implies that we keep a pencil and paper next to the bed, in case we wake up with a good idea. We might take a small piece of paper and short pencil when we jog, and a small digital recorder when we drive. Many people have noticed that ideas are fleeting and thus there is a benefit to always being ready to record them.

David N. Perkins and Robert J. Weber described the role of tactics in their work on invention. They listed ‘search strategies,’ which are used to seek out information and options. They identified the following:

- Sheer chance.
- Cultivating chance (searcher deliberately exposes self to wide semi-random input).
- Systematized chance (survey of a number of possibilities within a defined set).
- Fair bet (prototypes a possibility with expectations that it will work with modifications).
- Good bet (prototypes from principle and experience).
- Safe bet (derives by formal methods something that almost certainly will work) (1992: 321–322).

Weber individually described the invention and refinement of inventions such as the Swiss army knife and the chair. He listed the following tactics:

- Finding ideas in nature.
- Assemble (the parts or components) for complexity.
- Fine tune what you have.
- Repeat or duplicate a feature.
- Add a feature.
- Delete a feature.
- Rearrange features.
- Join independent inventions.
- Transform and change the scale.

Although Weber’s work was focused on invention, several of these strategies apply to all kinds of creative work. In fact, several parallel tactics are elsewhere recommended specifically for creative activities. *Finding ideas in nature*, for example, has been regularly suggested in the creativity literature. It is similar to other tactics as well, including ‘borrow and adapt’ ideas from others (appropriation), and even ‘find an analogy.’

The use of analogies may be particularly powerful: Eli Whitney developed the cotton gin after seeing a cat trying to catch a chicken through a fence; Samuel Morse apparently put stations in the telegraph after thinking about stagecoaches changing their horses periodically; Pasteur used an analogy of grape and human skin; the benzene ring may have been suggested by a dream of a snake biting its own tail; George Bissel used an analogy of a brine pump being used as an oil pump; James Watt was inspired to design the steam engine after observing a tea kettle; and Sir Marc Brunel borrowed from a worm for his work on underwater tunnels. Velcro and hundreds of other creative insights have resulted from the creative person finding apt analogies.

Many famous insights have resulted from a more direct borrowing strategy. Freud borrowed heavily from neurology and the medical model when describing the psyche; Piaget borrowed from biology in his theory of cognitive development; Darwin drew from geology in his theory of evolution. Musicians often borrow from various styles, the result being an original integration. Elvis Presley, for instance, apparently borrowed from gospel and country music. The Beatles brought an orchestra to rock ‘n’ roll. Apparently some of the best appropriations are from very different domains or styles.

Interpersonal Tactics

As was implied by the discussion above about procedures that can be used by parents, teachers, and supervisors, tactics can be interpersonal. Parents and teachers in particular should encourage children and students, but should be careful to avoid overjustification. This occurs when a person changes his or her opinion such that some activity that was initially intrinsically motivating becomes extrinsically controlled. Incentives and rewards are common extrinsic controls, and when individuals see them, they often assume that they are the reason for their actions—even if those same actions were intrinsically motivated moments earlier. This is especially disconcerting because intrinsic motivation is so often related to creative thinking.

Parents and teachers should shape confidence and ego strength as well. This is particularly important because original ideas are often unconventional, and children become quite sensitive to peer pressure in preadolescence. During that period they may shy away from their own original insights. If they have ego strength, they may maintain their originality and avoid common slumps that occur during this period.

Another interpersonal tactic is part of brainstorming programs. Participants in brainstorming groups are asked to generate as many ideas as possible and to postpone criticism. The participants are required to be careful of what they say to one another in an effort to maximize ideational output and minimize evaluation and inhibition. The tactic here is best summarized as 'postpone evaluation.' It is a postponement, not an elimination, because usually some evaluation or verification is needed, at least late in the creative process.

Admittedly, the empirical evidence suggests that brainstorming may not be the most effective use of time. Working alone may be better. When people are in groups there is a tendency toward social loafing, and people may assume that someone else in the group will complete the task at hand and thus not really invest much time or effort. Creative insights are unlikely when there is little investment of time and effort. But here again, it may be best to think of postponing rather than eliminating team work. Teams do provide diverse perspectives and resources that a person working alone may lack. Creative ideation is the most likely when an individual works alone, since there are no pressures on conventional thinking nor costs for thinking in an unusual way, but at some point teams may contribute to the refinement or implementation of the idea.

It may be very difficult to postpone criticism, as required for brainstorming. Humans are highly social animals and even if someone does not articulate a concern, usually people can read the signs and infer that their own thinking is being questioned by observers. But as noted above, it may be a good idea to postpone but not eliminate evaluation.

Most likely a balance of divergent thinking and convergent thinking will benefit the process as well. James March recommended something like this when he described a balance of play and reason. He suggested several tactics for finding a balance, including treating (a) goals as hypotheses, (b) intuition as real, (c) hypocrite as a transition, (d) memory as an enemy, and (e) experience as a theory. The last of these—experience as a theory—is another way of suggesting that we question assumptions.

March suggested that the five tactics be used alternatively, with a temporary suspension of 'reasoned intelligence.' In his words, "play and reason are functional complements. ... They are alternative styles and alternative orientations to the same situation. ... Our design problem is either to specify the best mix of styles or, failing that, to assure that most people and most organizations most of the time use an alternation of strategies rather than persevere in either one" (1987, p. 77).

The Wright brothers, Orville and Wilbur, used an interesting interpersonal tactic when they worked on the first flier: they argued. Wilbur and Orville would take opposite sides of some technical problem, debate the issue, then switch sides and debate some more. It was, then, an intentional, tactical technique that the brothers used to help solve the problems of flight. Very likely the argument tactic led to a questioning of assumptions and a consideration of alternative perspectives. Biographies of the Wrights describe how vehemently the brothers argued, but it must have been in the service of creative thinking because at some point they would switch sides and each argue the opposite view.

One kind of tactic is interpersonal but focused on avoiding rather than collaborating with others. I am referring to the contrarian strategy. Here the creator does what others are not. This works some of the time because creativity requires originality, and a contrarian will be original because he or she is doing what others are not. Examples include Jean Piaget, Sigmund Freud, Duke Ellington, and Pablo Picasso. This is, however, a difficult tactic because it requires discretion and careful moderation. If someone relies on contrarian tactics they could reinvent the wheel, even though if they asked, they would be told that the wheel already exists. If it already exists most people will not reinvent something—but a contrarian could go too far and do just that. Also, sometimes there is a good reason others are not doing something. It may be stupid, so people are not doing it. Originality is not sufficient for creativity, so contrarianism is not in and of itself adequate. It can be taken too far.

Conclusions

Tactics can be defined by (a) distinguishing them from strategies, which are general plans rather than specific in-process techniques; (b) distinguishing procedural information from conceptual and factual information; and (c) distinguishing cognition from meta-cognition. Tactics take various forms and can be of the let-it-happen variety or the more structured and effortful make-it-happen variety, although here there is some blur and the distinction is imperfect. Make-it-happen strategies may involve some relaxation and preconscious processing, in which case there is a let-it-happen component to them. Tactics can be personal or interpersonal; they can focus on the problem, as a kind of assimilation (e.g., 'turn it on its head'), or on the person who is dealing with the problem, as a kind of accommodation (e.g., 'change your perspective').

Tactics involving shifting one's perspective seem to be the most general. Some perceptual shift underlies many other tactics. The contrarian tactic, on the other hand, may require the most tact and discretion. This tactic did not always work effectively and might be best when used in moderation. Otherwise the result might be extreme but inappropriate originality, which is not synonymous with creativity. Very likely all tactics are best used with moderation and discretion.

'Talent' and 'creativity' are among the most influential watchwords of our time. When searched, they return billions and hundreds of millions of Google hits respectively. Many contemporary discussions center on how to define talent and creativity, and where to place them, in the modern marketplace of ideas. Both terms can indeed be traced far back into history, where conceptions have long been tied to the good, to the new and to prosperity. Ideals around talent in particular have shaped the ways disciplines are pursued and the ways social structures are organized.

This entry will explore modern interpretations of the terms 'talent' and 'creativity' in the context of their historical origins, showing how emphases across different periods have moved from virtue, to religious obligation, to culture (as a means to self-improvement), to genius, to more massified conceptions of everyday ability and creative expression. A brief survey of influential research will set up a discussion of some of the current issues surrounding talent and creativity. These include: the paradigmatic rejection of traditional talent evident in popular culture, the corporate global *war for talent* and creative people under neoliberal capitalism, the loss and acquisition of talent in an age of rapid technological advancement and social change, and new stratifications of skill and creativity in fields such as digital technology, biotechnology and data. The values currently attributed to talent and creativity in an increasingly globalized, digitalized and individualized world will be contrasted with older conceptions which more closely associated high levels of ability with fictional imagination, ethical action and virtue.

Historical Conceptions of Talent and Creativity

When Plato discussed the roles that natural human abilities play in society, he noted that the ideal polis was characterized by individual citizens pursuing worthwhile goals and skills which did not limit human flourishing (Irwin, 1995, p. 223). In his view there was a natural spread of gifts amongst citizens, equally distributed (in most fields) between men and women. While logically people were at different stages of development, under favorable circumstances progress from evil to good and from ignorance to knowledge could be made (*Phaedo*, 57a-118a). Plato noted that the proper cultivation of legitimate 'arts', such as medicine, carpentry, gymnastics and the military, was to be distinguished from a mere love of money. Aristotle's *technê*, in a similar fashion to Plato, associated the pursuit of talent with the ability to conceptualize proper ethical action. The ends of all activity, in Aristotle's view, aim at some good; but the question is how that good affects the individual and the society (*Nic. Ethics*, 1094a1-2). In Western culture, talent and the ability to create *new action* were from this early point set in the context of virtue.

Plato discussed creativity (not in precise terms, but its essence) with respect to the talents of the epic and lyric poets and the performances of dancers and rhapsodies. While he was highly skeptical of the contribution and value of artists, the imaginative capacities of poets he explained as deriving from a spiritual state of being inspired and possessed by divine forces.

And as the Corybantic revellers when they dance are not in their right mind, so the lyric poets are not in their right mind when they are composing their beautiful strains ... For the poet is a light and winged and holy thing, and there is no invention in him until he has been inspired and is out of his senses (*Ion* 534a).

This is relevant to modern thinking in that Plato might have agreed that talent is to be found across nations, races and genders (*The Republic*, IV 332e), but creativity—rather than being abundant in all people or fields—was other-worldly. Put another way, while citizens in the polis were encouraged to better themselves and pursue their talents, the creative powers that brought about imaginary worlds or transformative ideas were not necessarily found in everyday practice and engagement. Notably, the Romans did expand the concept of creativity to other artists such as painters and had a specific word for the human creator: *creatio* (Tatar-kiewicz, 1980, p. 246). The Latin origin of the word *genius* characterized innate ability or inclination as an "attendant spirit present from one's birth" (Colman, 2015, p.312).

Talent was also discussed in ancient Chinese philosophy, which emphasized directing effort towards one's passions. Confucius claimed that "talent is hard to find" (*The Analects of Confucius*, VIII) and like Plato and Aristotle, related talent to virtue: "The junzi (gentleman) does not accept being known for petty talents but accepts receiving great burdens. The small man (villain) does not accept receiving great burdens but accepts being known for petty talents" (Book 15). Creativity, in Chinese philosophy, was an ideal linked to exemplary intention and good character, which positively impacted the environment (Niu, 2012). Showing how these concepts have sparked renewed interest in recent years, Christine Gross-Loh noted that hundreds of Harvard students were being drawn to Chinese teachings which painted "heart" and "mind" in a synonymous context, which in turn allowed them to think differently about how they pursued their own talents (2013).

In the Christian period, as historian Wladyslaw Tatarkiewicz explained, creation from nothing (*creatio ex nihilo*) was understood as only the domain of god. Men made art but were not capable of *creating* (1980, p. 247). Before the 14th century, talent was referred to denotatively as a noun, a unit of weight and then of currency i.e. 'a talent of silver' (Adamsen, 2016, p. 77–78). In the Parable of Talents (Matthew 25: 14–30) talent referred to both a unit of currency, and the skill (also natural ability, endowment and responsibility) of making profit in the marketplace. As Justin Ukpong argued, the parable can be read in both theological and social-historical contexts, either as a confirmation of the two servants who trade and thus serve god's kingdom; or of the punished and rejected third servant who buries his one unit of talent (metaphysically suppressing his abilities). The parable also embodies the Christian ideal of the meek, "prophetic voice" who shows subservience to god (Ukpong, 2012, pp. 191–192). Holden and Tansley note that from the Middle Ages, definitions of talent morphed from associations with units of weight and currency into increasingly metaphysical realms, designating innate capacities and outstanding accomplishments in mental and physical realms (2008).

Towards the end of the Enlightenment Jean-Jacques Rousseau lamented what he saw as the separation of talent from virtue, and of skill from morality: "we no longer ask if a man has integrity, but if he has talent, nor whether a book is useful but if it is well written ... There are a thousand prizes for fine discourses, none for fine actions" (2012, p. 31). By contrast, the 19th century German concept *Bildung* emphasized culture as the path to self-improvement. Culture, especially as denoting engagement with the world, learning, experiencing and forming skills such as language and custom designated "the properly human way of developing one's talents and capacities", or what is "given" (Gadamer, 2004, p. 9). Immanuel Kant, as Hans-Georg Gadamer noted, spoke of the duty one has to oneself to cultivate a natural talent, but *Bildung*, he argued, is more than a means to an end; it is an inward, almost spiritual process of development. One requires *Bildung* to form the ideal image of a human; a character with cultivated gifts as an acting being (Gadamer, 1975, pp. 9–13).

In each of these philosophical contexts, the learning of craft, formation of skill and acquisition of knowledge—in other words, the cultivation of talent—had some relationship to ethical action. By the 18th and 19th centuries however, more individualized interpretations of talent and creativity had emerged. William Deresiewicz has written of the trajectory of artists from artisans to geniuses; that the solitary virtuosos of the Romantic era offered "higher truths" to the elite class in a more secularized, post-revolution world. Creative and supremely talented idols such as Blake, Goethe and Beethoven represented a new creed of artists as the sole creators of originality, which led to the recognition of later figures such as Picasso and Wagner as cultural aristocrats. Linguistically it is important to note that only from the 19th century was the term 'creativity' commonly used to describe the practice of artists: "not only was it (art) regarded as creativity, but it alone was so regarded. 'Creator' became a synonym for artist and for poet" (Tatarkiewicz, 1980, p. 249).

In the 20th century however, art to a large extent became institutionalized. Museums, galleries and universities transformed the artist into a middle-class professional and, with the help of other cultural forces, artists' spiritual aristocracy was demystified (Deresiewicz, 2015). From the beginning of the 20th century the sciences and nature also came to be recognized as creative, which for some was seen as a transference of "concepts proper to art" (Tatarkiewicz, 1980, p. 249). These shifts were an important precursor to later twentieth-century conceptions of talent and creativity which saw much broader dissemination of the terms, and indeed, in some popular culture domains, the rejection of traditional ideals of excellence for more personality-oriented, mediated presentations of selfhood.

Contemporary Research on Talent

Research on talent and creativity in the second half of the 20th century and early twenty-first century not only broadened conceptions from the lone intellectual or artistic genius but helped challenge models for identifying talent and creativity. Many varied categories of giftedness have now been established, some of which assert that academic ability—especially as judged by schooling systems of grades and tests—is not synonymous with creativity, or potential for high-level performance. Margaret Heffernan cited the important examples of Richard Branson, Whoopie Goldberg and Jamie Oliver who were not recognized as having 'conforming' creative potential in their youths (BBC Radio 4, 2017). Their experiences illustrate how notions of talent were liberated from more rigid, aristocratic and singularly artistic definitions.

Research on talented individuals has also paid close attention to how different environments affect the identification and nurturing of natural ability and thus promote or limit creative potential. Jane Piirto's framework examined genetic, emotional and cognitive aspects, as well as the social conditions and support environments for talent which she calls "the suns" (2000). The three major suns, or spheres of influence on talent are: home, community and culture, and educational institutions. James Flynn, famous for the Flynn Effect study which found that intelligence increased over the course of the 20th century, also stressed

that external non-cognitive factors could cripple talented or intelligent people. Flynn furthermore noted that educational institutions were potentially less productive for talent development than the cognitively demanding modern world of work (as noted in his study of Dutch adults, adolescents and children, BBC Radio 4).

A key characteristic of successfully nurturing innate ability is the concept of “flow” coined by Mihaly Csikszentmihalyi (1990). Flow refers to a deep state of engagement, concentration, tenacity, sense of enjoyment, of control and of being rewarded by an activity. MacDonald, Byrne and Carlton’s empirical study applied the conditions necessary for flow to musical composition. These conditions included: clear establishment of goals, immediate feedback, a balance between challenge and skill and reduced fear of failure (2006, p. 296). They confirmed that high levels of flow correlated with high levels of creativity (p. 300). In another study on team flow in business settings, van den Hout, Davis and Weggeman compared the code words, actions and phrases used by teams in sports settings to business. Considering how this communication allows teams on a field to function as a blended, cooperative whole (2018, p. 391), he noted that “For managers, the key is to know how to build a team of people with a mission and complementary skills, and then empower them to develop the prerequisites of team flow” (p. 413). In such settings the combination of individual talent and a group dynamic with flow characteristics can lead to even higher levels of creative output.

Abraham Tannenbaum (1983) focused on the field of gifted education and the character of creatively talented individuals. Observing that there are socially disapproved types of talent such as Machiavellianism and demagoguery, he broadened definitions of giftedness beyond intellectual ability to include skill that “enhances the moral, physical, emotional, social, intellectual or aesthetic life of humanity” (p. 86). Like Piirto, who defines talent in terms of domain-based skill (the rules for which are determined by established experts) and as that which reflects an inborn propensity to perform or demonstrate predictive behaviors in a certain domain (2010), Tannenbaum also referred to the complex external and environmental forces influencing talent. He stressed however that *developed* talent is displayed only in adults. Gifted children show the potential for becoming recognized in various domains when they exhibit traits such as superior general intelligence or special aptitudes in other areas. Tannenbaum’s developed capacities were further divided into categories ranging from “scarcity talents” which produce major breakthroughs transforming fields such as science and medicine to “anomalous talents”, which pertain to small-scale skills such as cooking and gardening (1983, p. 59-60). Such variation in the possibilities of identifying talent corresponds to discussions of big C and “little-c” or “mini-c” creativity (Beghetto and Kaufman, 2007), where scaled categories reflect different degrees of significance.

Francoys Gagné’s 1993 survey of 20th century definitions of talent showed how researchers such as Guilford, Gardner and Taylor (among many others) helped to extend thinking about established, specific domains of talent. Like Tannenbaum, Guilford and Taylor also emphasized that recognition of creativity need not necessarily be limited by scholastic intelligence scores (see Gagné, 1993, p. 69). Guilford’s Structure of Intellect Model distinguished various types of operations (such as memory retention and evaluation), products (such as systems and implications), and contents (visual, auditory, symbolic, semantic, behavioral) to create a psychometric testing model measuring 180 intellectual abilities or factors (1956). Gardner’s seven types of intelligence included the linguistic, the musical, the logical-mathematical, the spatial, the bodily-kinesthetic, as well as two personal intelligences, the intra-personal and the interpersonal (1993). Taylor’s 1967 Multiple Talent Approach, largely devoted to possibilities for teaching in the classroom with a focus on workforce skills, categorized talent into the following fields: academic, productive thinking, communicating, forecasting, decision-making and planning. Gagné’s own work proposes that human abilities can be grouped according to: behavioral domains (e.g. perception, social and affective behaviors); occupational fields (e.g. arts and sports); and degrees of development—from natural aptitude to systematically developed abilities (1999). Gardner and Taylor’s models are still commonly referred to in contemporary discourse around critical thinking and creativity.

Current experts in the field such as Heffernan (BBC Radio 4, 2017) and Carol Dweck (2016) have more recently suggested that the notion of fixed talent itself is unhelpful. This is because traditional systems of identifying potential in schools, universities and professional interviews have proven to be poor indicators of performance. “Believing that talent is precious and rare is wasteful because it writes off most people” said Heffernan (BBC Radio 4, 2017). Rather, as revealed in Heffernan’s interviews with experts such as Laszlo Block (former head of Google’s ‘People Operations’) factors that lead to exceptional creativity, high job performance and longevity tend to be: tenacity, grit, resilience, comfort with ambiguity, a growth mindset and courage to challenge ideas and authority (BBC Radio 4, 2017).

The Paradigmatic Rejection of Traditional Talent and Expertise from the Late 20th Century

While academic studies in recent decades have remained committed to nuancing understandings of giftedness, conceptions of the value of creative skill and talent in certain domains of popular culture have shifted dramatically. In the late twentieth-century the vast democratization of entertainment and proliferation of video technology brought with it the celebrification of everyday, ordinary citizens across a range of mediums. In the US especially, fame spread to criminals, doctors, lawyers, body builders, radio jockeys, religious figures, politicians, actors in television commercials, a wide variety of musicians and many other individuals who were able to attract and sustain media attention. These figures differed markedly from their famous predecessors in highly theoretical, rigorous fields of art, science and politics (such as Mozart, Marie Curie and Abraham Lincoln - known for contributions of history-defining oeuvres and masterpieces) in that they were *famous for being famous*, to invoke Daniel Boorstin’s well-worn cliché (1971).

Media flashpoints, especially in the 1990s, such as a kidnapped child, a corporate lawsuit, a celebrity divorce or murder (the case of O.J. Simpson is an often-cited example) or the death of a musician captured public fascination and created cultural obsession around mediatized reality and identities (Turner et al., 2000, p. 2). Importantly, the focus was usually not on individuals' natural gifts, displays of excellence in a specific field or creative influence. Idolatry had morphed into consumption-oriented engagement driven by emotional narratives and the commodification of self-hood—as later figures such as Kim Kardashian would come to exemplify. When asked in a *60 Minutes* interview what her talent was, Kardashian replied: “it is a talent to have a brand that’s really successful, off of getting people to like you for you” (Kim Kardashian facing backlash after 60 Minutes interview, 2016). Under definitions of entrepreneurial creativity (see Della Corte and Del Gaudio, 2017) Kardashian innovatively generated new products, services and organisations through technological forms of creativity (reality television and social media), capitalizing on and revolutionizing modes of consumption under free market capitalism.

With the proliferation of content required to fill the 24-h news cycle came the need for an endless supply of television ‘talent’ or participants. The thematic focus on voyeurism in confessional television programs such as *Jerry Springer* (1991–present) and *Ricki Lake* (1993–2004) and early surveillance-based comedies and dramas such as *Candid Camera* (1948–2014) and *COPS* (1989–present, featuring police patrolling for and arresting criminals) relied on idiosyncratic, bizarre, controversial, dangerous and excessively emotional or sensational performances. The paradigmatic shift that occurred, especially with the explosion of reality television hits such as *Survivor* (2000–present) and *Big Brother* (2002–present) and other shows which exhibited the “theatre of neoliberal capitalism” (Couldry, 2008) such as *Dirty Jobs* (2003–12) and *Undercover Boss* (2010–present), was that as viewers co-produced content, they were more often than not cast because of a lack of performing or acting talent. However, while surveillance-competition shows often emphasize hostility, weakness, pettiness and exclusion, a renewed interest in talent (albeit a style of talent which suits a certain kind of mockery entertainment performed by celebrity judges) has been evident in other formats such as *Dancing with the Stars* (2005–present) and the *Got Talent* franchise (2006–present).

The cult status of individuals on newer performance platforms such as YouTube and Instagram highlights the complexities of a new era in the celebration of talent and creativity, as stars masterfully infuse the ability to sell with internet-tailored exhibitions of dynamism and authenticity. While some stars with high internet visibility such as soccer player Cristiano Ronaldo are world-class in long-established domains such as arena sports, for other figures who skillfully inhabit creative technology spaces, such as James Charles and Liza Koshy, talent appraisal centers more explicitly on the performance of personality. Indeed these figures generate value through extending and challenging audiences’ perception around social (and political) topics, in ways that are not necessarily decorrelated from, but are certainly striking, when compared to classical notions of the (divine or artistic) ability to create something transformative or artistically imaginative from nothing. While technology has provided so many people with the means to explore their creative ability and show their talents in popular culture, one consequence is that traditional or historical forms of excellence in fields such as music, art, academia, science and other domains have become less central in modern society due to the volume of competing material. Importantly, online social platforms have also become a key portal through which to criticize and shame individuals, often shifting focus away from skill-based or creative contribution and more toward the vilification or humiliation of individual personalities.

The democratization of talent and proliferation of technological and entrepreneurial creativity has undoubtedly made the terms for appreciating and recognizing talent fairer. But the valuing of so many variations and degrees of skill or craft as *creative* in an unregulated, para-social environment may also risk obstructing socially, ethically and democratically structured standards of talent and creativity. The most poignant cases of this have been seen in the way politicians in the US and the UK for example have popularized socially harmful messages by delivering them entertainingly. Their success in doing this infers talent and creative use of technology, at least in the field of demagoguery, but resulting policies and social changes arguably damage much of the cultural fabric (such as multicultural agendas and recognition of differently abled people) required for nurturing talent and creativity.

The Scarcity of ‘Talent’ in Twenty-First Century Markets

As Brown and Tannock described, “corporate and national policy debates are being framed around the view that intense economic competition has sparked a ‘war for talent’” (2009, p. 377). The war for talent has been characterized as increasingly subject to strategy derived from data, where analysis can help determine which individuals will be successful in the new business structures emerging in high-tech and knowledge-intensive industries. As the world has *gone flat* in terms of the search for talent, traditional geographic, gender and class barriers are disappearing. This has created a different playing field for recruiters, as education standards, training and skill benchmarks transition from nation-based to global paradigms.

Human creativity, according to Kiran Prasad, LinkedIn’s vice president of engineering is increasingly measured by the ability to innovatively dissect, evaluate and present data. Prasad noted that there is an ongoing risk that sought-after skill sets will continue to change rapidly in the future, soon making even presently specialized, in-demand roles such as ‘data scientists’ obsolete (McKinsey and Company, 2015). Yuval Noah Harari noted in 2018 that as machines gradually develop the cognitive skills to compete with humans (surpassing their previous manual competitiveness) artificial intelligence will continue to improve, “and even jobs that demand high intelligence and creativity might gradually disappear” (Harari, 2018).

With forty million workers currently unemployed globally, there is already a “short supply” of people with the required new skills in the rapidly evolving job market, as a recent report by Oxford Economics stated (2012, p. 2). At risk especially are ‘low-skilled’ occupations such as drivers, manufacturing workers and retail cashier positions which are increasingly automated. Analysts

also predict that many white-collar roles in business, legal and medical industries will either disappear to automation or require significant ‘upskilling’. The prospect of large numbers of workers successfully developing such skills in adequate time may prove challenging, as technology advances more rapidly than domains of talent can be established, and as the purpose of so many new jobs is to automate the existing workforce to meet productivity and profit objectives. Harari has questioned how an emerging ‘useless class’ will be able to cope: the ever-changing requisites of talent to perform the remaining roles for humans may be beyond the learning capacities, emotional resilience and stamina levels of many people (2018).

Workers from more diverse corners of the world are however gaining access to the global job market. The ‘brightest’ and the ‘best’ are being hired in the war for talent regardless of nationality, gender, ethnicity or social background, as Brown and Tannock explain (2009, p. 377). While talent is trumping geography (2009, p. 380) and those who possess distinctive skills in the new economy are increasingly mobile, the pitfall is that nationally-focused systems for educating and nurturing talented people will be absorbed into global meritocracy institutions: “for why should a country invest in education if it is easier and cheaper to import already educated workers from abroad?” (Brown and Tannock, 2009, p. 385). What appears to be lacking in the forthcoming meritocracy system is the ability to separate or delineate modern notions of talent and creativity from economic and technological objectives.

Creative Talents Lost and Gained as a Result of Hyper-Technology

Technology is permitting vast numbers of people across the globe to lead more convenient and stimulated lives and to pursue new forms of creativity. Access to information has never been so widespread, infinite or equal and types of talent and creativity are constantly being redefined (see Richard Florida’s highly influential work on the creative class, 2003). The work now performed by machines, from navigation to project management to curating and distributing educational material, leaves ever-increasing free time to focus on honing natural gifts and talents and to apply those skills to creative projects. New jobs in ‘experience design’ and ‘machine learning engineering’ in the technology industries require humans to acquire new talents such as programming scalable computing environments and refining and reading algorithms in their software code (ICD InfoBrief, 2018). In medicine, roles such as ‘reconstructive surgery 3D printing specialists’ and ‘epigenetic counselors’ demand specialized new skills as the processes involved with performing these roles become more complex. Epigeneticists for example possess highly specific talents in charting heritable changes that affect gene activity and expression (Hamilton, 2011).

However, according to UCLA distinguished professor Patricia Greenfield skills such as critical thinking and analysis have declined in the period of hyper-technology, while visual literacy has improved (2009). Basic skills including spelling, numeracy and conversational adeptness are also reported to be in decline (Drago, 2015). Furthermore, creative performance traditions such as those handed down through Australian Aboriginal (Grant, 2014) and African (Awogu-Maduagwu, 2018) dance, singing and storytelling are disappearing as culture, in some respects, becomes more homogenized. As Abbie Smith Rumsey argued, in response to the datafication of artifacts, artworks, literature and other records our first task is “to rescue the past—the full legacy of human knowledge built up over millennia now living in libraries, archives, museums and in people’s homes. Today—and certainly 20 years from now—the first place people look for information, and often the last, is online” (2016). Across the physical spaces Rumsey mentions are also the records of talents; learned, practiced and mastered by generations whose work and hobbies were defined by application to such traditions.

In thinking about the virtue implicit in language around talent and creativity it is important to note that shifting modes of sociality (to digital spaces) and new, highly specialized talent domains pose challenges in terms of social wellbeing. Pew Research interviews for a study titled ‘The future of wellbeing in a tech-saturated world’ with experts such as Rob Reich (Professor of Political Science at Stanford University) suggested that a net harm overall will be felt over the next decade due to loss of privacy and security. Issues include “a degraded public sphere and its new corporate owners that care not much for sustaining democratic governance, the technological displacement of labor due to AI and decreasing dynamism and political autonomy due to additive technologies.” Rich Salz, principal engineer at Akamai Technologies, similarly pointed to “more isolation, less ability to focus, more ability to be deceived by bad actors (fake news) and so on”. Leora Lawton, lecturer in demography and sociology and executive director of the Berkeley Population Center and David Ellis, PhD, course director of the department of communication studies at York University in Toronto echoed these concerns. According to these experts, digital services and devices will keep harming individual welfare and tearing up the social fabric. Welfare concerns specifically include depression, loneliness, video-gaming abuse and even suicidal behavior, especially among teens and young adults (Anderson and Rainie, 2018). These predictions, however, should be considered in the context Euro-centric anxieties about the quality of life as the world becomes more globalized and developing countries advance. They should also be reviewed with regard to previous studies by Piirto, Flynn and others demonstrating how prohibitive external factors affect the nurturing of talent and creativity.

Conclusion

In ancient philosophy, it was acknowledged that people possessed a wide range of skills and talents and that everyone had the potential to improve. From this it should not be construed that ancient societies were fairer or more democratic than those that exist today, but that the intellectuals of the time theorized about the ethical value of talent and creativity. To be creative was to

invoke higher powers of character or divine spirits to bring about that which was imaginative or transformative. While theoretical knowledge (such as mathematics) was technically accessible to everyone to different degrees, knowledge of good action (or virtue/technê) required a different form of talent. Perhaps most pertinent was the notion that the cultivation of abilities should not obstruct the basic needs of human life.

Later periods saw ideals of creativity and talent transferred to aristocratic artists and intellectuals, to professionals and celebrities, and to everyday people. Now there is a new talented elite: the technologically-skilled creative class. Research in recent decades has recognized more specifically defined fields and factors that affect talent creativity, and clearer distinctions have been made between talent and IQ. In popular culture the pursuit of excellence in traditional performing has had to compete with commodified spectacles of personality. Some of the most impacting displays of talent have been designed to exploit voyeurism and incite racially charged populism generating discourse in which virtue is particularly undervalued.

The modern world of work now requires a range of exciting new talents to propel ever-more complex expressions of creativity. A more connected world has the potential to showcase and acknowledge more talent and creativity. But questions remain as to how new talent fields and creative projects will benefit individual societies and the global population, and how, if at all, they will relate to traditional concepts of fictional imagination, ethical action and virtue.

Introduction

For most of its history as a topic of interest to psychologists, creativity was thought of as a domain general skill (or set of skills). The cognitive skills underlying creativity were therefore assumed to be largely the same regardless of domain. Creativity testing and creativity training were likewise approached from an assumption that creativity was domain general. That belief about the nature of creativity only began to change toward the end of the 20th century.

In 1998 the *Creativity Research Journal* published the first Point-Counterpoint set of articles in the journal's history. The issue that prompted this debate was whether creativity was domain specific or domain general. But even when making an argument for domain generality twenty years ago, [Plucker \(1998\)](#) acknowledged that "Recent observers of the theoretical ([Csikszentmihalyi, 1988](#)) and empirical ([Gardner, 1993](#); [Runco, 1989](#); [Sternberg and Lubart, 1995](#)) creativity literature could reasonably assume that the debate is settled in favor of content specificity" (p. 179). A few years later, in his 2004 *Annual Review of Psychology* entry on "Creativity," [Runco](#) argued that the concept of domains "must be acknowledged because most of what has been uncovered about creativity is domain specific" and "clarifying these differences is one of the most important impetuses in the literature" (p. 678).

The issue of domain specificity is discussed elsewhere in this encyclopedia (See Domains of Creativity) so this entry will simply assume that creativity is for the most part domain specific without further explanation. That said, most of the work that has been done in creativity training has been done under the assumption of domain generality, and, as will be shown, that work is still important for three reasons:

1. The approaches most commonly used today to teach creativity are still the same ones invented decades ago.
2. Many of those approaches, even though conceived under a domain general framework, can be applied to domain specific creativity training by careful selection of the content of the training exercises used.
3. There has not yet been a great deal of research in the area of domain specific creativity training (Even if such work had been done, of course, it would be beyond the scope of an encyclopedia entry to catalogue for every domain how to teach creativity in that domain. A few examples will therefore have to suffice.)

In their meta-analysis of 70 studies of the effectiveness of creativity training, [Scott et al. \(2004a\)](#) noted two "overarching assumptions [that] shape the content and structure of creativity training" (p. 362):

1. Whether the training is a model-based approach, such as the Osborne-Parnes CPS Model discussed below, or relies on "theory independent techniques, such as brainstorming" (p. 363) to develop divergent thinking skill.
2. Whether training is based on general models "held to enhance creativity across a range of situations that require little modification to account for domain and population differences," or if effort is made to "tailor techniques and models to the unique demands made in a given performance domain" (p. 362). They give one example of this kind of domain specific training, which will also be discussed below.

Overall their meta-analysis found that "more successful programs were likely to focus on development of cognitive skills and the heuristics involved in skill application, using realistic exercises appropriate to the domain at hand" (p. 361).

[Scott et al. \(2004b\)](#), in an analysis of a somewhat larger but less selective sample of training programs, found that divergent thinking (idea production) training was the most commonly used creativity teaching technique, sometimes combined (as in the CPS model) with evaluative thinking practice. Mental imagery training was also common in the studies they reviewed. They found that "some types of training, specifically idea production and cognitive training, proved particularly effective while some commonly applied training strategies, specifically imagery training, proved less effective" (p. 149).

Although these two meta-analyses demonstrated that creativity training can be productive, the assumption of domain generality has hindered the develop of better domain specific methods for nurturing creativity. To understand how much an assumption of

domain generality has handicapped the teaching of creativity, consider this question about the development not of creativity but of more basic skills:

How does one teach a novice a new skill or help someone develop and improve a skill that person already has?

The words “It depends” will almost certainly frame any answer one might give. Teaching a novice a new dance step, teaching a novice how to design a bridge, and teaching a novice how to play a card game would be such different things that it is hard to see how any one answer might apply to all three. Ditto for helping a skillful pool player learn how to line up a bank shot, helping an eager student develop better note-taking skills, and helping a very talented young poet learn a new poetic form. Each will require a different teaching method and (perhaps) a different training regimen.

Is there nothing one can say about all, or at least most, kinds of skill training? How about:

- It is often helpful to break a complex skill down into smaller parts.
- Honing skills usually takes a great deal of practice.
- Distributed practice is generally more effective than massed practice.

Those three things are certainly not true for all kinds of skill development, but they are probably true in teaching many skills — enough so that teacher preparation programs typically share these ideas with prospective teachers. General heuristics such as these hardly constitute a training program, however, because the details of the particular skill will certainly be more important. If one had nothing else to go by, however — if one knew nothing more about how to help a student develop some particular skill — these very general recommendations, while weak, might still be useful heuristics to bear in mind. They might also help guide the development a program aimed at developing a specific kind of skill.

This is the current situation of creativity training in most domains. There are some very abstract heuristics that might be useful in nurturing creativity in many domains but that are primarily of value only when tailored to a specific domain (just as the suggestion that “It is often helpful to break a complex skill down into smaller parts” has training value only if one can tailor it to a specific skill). For this reason, this entry will discuss two of the most widely used and best researched approaches to teaching creativity as a domain general skill and then discuss how these approaches might be adapted to teaching creativity in specific domains.

Divergent Thinking Training

There is an unsurprising similarity to most creativity-training programs. Virtually all include heavy doses of what Guilford labeled “divergent thinking” (1956). Consider the following popular approaches to creativity training:

- CPS (the Osborn-Parnes Model of Creative Problem Solving), where the emphasis is on withholding judgment, going for wild ideas, and following the other dictates of brainstorming;
- Talents Unlimited, where the oft-repeated instructions are to find “many, varied, and unusual” ways to do or think about something;
- Syntectics, where the key idea is simply (but this is never simple) to “make the familiar strange” (Syntectics, 1968).

Divergent thinking involves the production of many ideas in response to an open-ended question or prompt. Knowing what has now become common knowledge — that creativity requires going beyond the known, boundary breaking, risk taking, finding new and unusual ideas — it is not hard to see why Guilford believed divergent thinking was a central part of creativity or why those who wished to assess creative potential have often developed tests of divergent thinking (Runco and Acar, 2012).

The important role divergent thinking plays in creative performance may seem obvious now — it is hard to think about the field of creativity theory and research without referencing this seminal idea — but it was hardly obvious when Guilford proposed it in the 1950s. He identified four parts of divergent thinking:

- fluency (the ability to produce great number of ideas);
- flexibility (the ability to propose a wide variety of ideas);
- originality (the ability to produce unusual and original ideas); and
- elaboration (the ability to develop, expand on, and flesh out an idea).

Divergent thinking is not the alpha and omega of creativity training — when it has been, such programs have sometimes been derided as mere fun and games — and it has not always proven as powerful as its proponents have assumed, but it remains central to most systematic efforts to teach creativity. The most commonly used method to facilitate divergent thinking is brainstorming. Here are the rules:

- *Defer judgment.* The goal is to produce a large quantity of ideas without regard to the quality of ideas (with the assumption that quantity will lead to quality). Deferring judgment means not criticizing ideas (both those of others but perhaps even more importantly one’s own ideas), because criticism leads to more self-censorship and less risk taking. Deferring judgment also means not praising ideas, because once ideas are praised, the element of judgment has been introduced, which will also limit the

free expression of ideas. Judging ideas is not dismissed as unimportant but is simply deferred until later, as a separate step in the process of developing ideas or solving a problem.

- *Avoid ownership of ideas.* All ideas belong to the group. When people feel that an idea is “theirs,” egos can get in the way of creative thinking (and people are likely to be defensive later when ideas are critiqued). When people feel they own ideas they are less willing to allow their ideas to be modified, as in the next rule.
- *Feel free to “hitchhike” on other ideas.* This means that it’s okay — more than okay, it’s encouraged — to borrow elements from ideas that have already been offered and to take ideas already suggested and make slight modifications to them.
- *Wild ideas are encouraged.* Impossible, crazy, totally unworkable ideas may not be where the group will want to end up, but wild ideas often lead someone to think of other more workable ideas. It’s much easier to take a wildly imaginative bad idea and tame it in ways that fit the constraints of an actual problem than it is to take a routine bad idea and turn it into something interesting.

Divergent thinking can be used as part of a larger creative problem solving process (such as CPS, in which each step of the model includes both a divergent-thinking phase, which usually involves brainstorming, and an evaluative thinking phase, in which ideas are compared and judged). It can also be used to aid knowledge acquisition (as discussed in the **Teaching for Creativity and Teaching Content Knowledge** section below). It can also be used alone to build up and exercise divergent-thinking “muscles” — but the nature of those “muscles” is important, and leads us into the key question of the section, **Divergent Thinking and Domain Specificity**: How domain specific are divergent thinking and creativity, and what does this mean for teaching creativity?

CPS

The most widely taught complete model for teaching creativity is the Osborn-Parnes CPS model. As already noted, each step of the model involves a divergent thinking phase followed by an evaluative phase in which problem solvers decide which of the ideas produced should be carried over to the next step in the process.

The model itself has many variations; as its official website notes, “If you search the Internet for “Creative Problem Solving,” you’ll find evidence of many variations, all of which may be traced back to the work that was started by Alex Osborn in the 1940s, developed with Sid Parnes in the 1950s, and nurtured at SUNY Buffalo State and the Creative Education Foundation” (<http://www.creativeeducationfoundation.org/creative-problem-solving/the-cps-process/>). The version described here is typical of the many variants, which differ only in fairly minor details or nomenclature.

1. *Mess-Finding* means being open to experience, freely exploring opportunities, looking at old solutions in different ways, and thinking about things one might like to change (either because the current situation is somehow unpleasant, or because one senses that a tolerable or even pleasant situation could be improved). This is the divergent thinking phase. The evaluative thinking phase of Mess-Finding is the acceptance of some challenge, some situation that one has decided to try to improve.
2. *Data-Finding* is gathering information about the situation. This includes the kinds of things we normally call facts (Who, What, When, Where and How kind of facts), and it also includes impressions, feelings, and other very subjective kinds of information. This is not a search for solutions, but it may involve considerable analysis of the situation. The goal of Data-Finding is to understand the current situation, including its problematic aspects, as thoroughly as possible. After brainstorming produces an abundance of such data, the problem solver evaluates the list he has created to determine which are most important to bear in mind in the next steps of the process.
3. *Problem finding* is a search for the best way to frame the problem in terms of what it is one wishes to achieve. Problems are typically stated in the form of “In what ways might I... ?” or “How might I... ?” because this kind of phrase forces the problem solver to think about where she wants to end up, not how she will get there. As in every step in the process, the problem solver first focuses on a wide range of possible problem statements (using divergent thinking) before narrowing this down to the best such statement (evaluative thinking).
4. *Idea-Finding* means developing and listing a wide variety of possible solutions to the problem statement (divergent thinking), then narrowing down the list to just a few (evaluative thinking).
5. *Solution-Finding* is a continuation of the winnowing process begun in Idea-Finding. The goal is to find a way to evaluate the promising and interesting ideas that one came up with during Idea-Finding. The difference between Solution-Finding and the evaluative part of Idea-Finding is that in Solution-Finding, explicit criteria are developed to evaluate ideas (divergent thinking phase). Then those criteria are applied, and an optimal solution is found (evaluative thinking phase).
6. *Action-Planning* is the final step. It includes looking ahead to assess possible sources of assistance and resistance, implementing the solution, and monitoring progress along the way to determine how well the plan was working and what adjustments might be needed. Sometimes Action-Planning results in new challenges — new messes — which takes one back to Mess-Finding.

Divergent Thinking and Domain Specificity

Domain specificity theory argues that creativity varies by domain and that most of the skills that underlie creative performance in one domain are of little importance in other domains. Just as developing skills and acquiring the kind of content

knowledge that will make one an expert in one domain (e.g., auto mechanics) will have little impact on one's expertise in an unrelated domain (e.g., ballet), so it is with creativity-relevant skills (including, but not limited, to divergent thinking). Developing creativity-relevant skills can only happen domain by domain. This parallels how skill development and knowledge acquisition must be taught in most contexts. Teaching students U. S. history is unlikely to have any impact on what they know about physics (and vice versa). In fact, teaching students U. S. history is not even likely to have much influence on what the students know about other areas of history, such as ancient Japanese history or modern Egyptian history, although there could well be similarities in the kinds of research and interpretations students encounter in this within-domain example. Teaching tends to be very domain specific when it comes to content knowledge, and the same is true (according to domain specificity theorists) of creativity.

Content knowledge is typically taught domain by domain — noting, wherever possible, linkages among domains. Most critical thinking skills must also be learned domain by domain, and creative thinking skills include critical thinking skills. Despite its emphasis in creativity training programs, creative thinking isn't just divergent thinking, isn't just coming up with many possible responses to open-ended problems or opportunities. Creative thinking often requires original and unusual ideas, but it also requires determining which ideas will work, which fit the constraints of the situation, and as such productive creative thinking relies on clear critical thinking. And critical thinking skills tend, like content knowledge, to be largely domain specific.

Here's an example using one of the most widely taught critical thinking skills (and one that is often essential for creativity), analysis. One can teach students to analyze a sonnet, analyze a geometric proof, analyze white light by dispersing it with a prism, analyze tree rings, analyze historical documents for evidence to support or refute a theory, analyze the formal elements of a work of art, analyze a rock strata, analyze computer code, analyze a philosophical argument, or analyze the structure of a musical composition, but one cannot simply teach "analysis" as a general skill and expect students to apply it in all areas. Teaching analysis means teaching analysis in many different domains, with little anticipated overlap.

So it is with all of the thinking skills that underlie creativity, including divergent thinking. Just as we can lump together many very different skills under the label "analysis," even though they are actually many very different domain-specific skills, the same is true of divergent thinking. Different kinds of analysis, like different kinds of divergent thinking, may have a similarity when viewed, as it were, from the outside. But from the inside — from the perspective of the thinker — they are quite different. Being able to do one kind of analysis or one kind of divergent thinking does not mean one can do other kinds of analysis or divergent thinking. If a teacher's primary goal is to promote student creativity in a single domain (e.g., in a creative writing class), then focusing one's teaching activities on that domain is most appropriate. If the goal is to promote student creativity in multiple areas, however, it is essential that the creative-thinking exercises (including divergent thinking exercises) use content from a wide range of domains.

This domain specific creativity training effect has been shown in experimental divergent thinking training studies, where one domain has been targeted, as well as in descriptive studies that have look at correlations of creative performance across domains (Baer, 2016). For example, in a study in which middle school students received divergent thinking training with only poetry-related exercises, students later creative performance was significantly greater when writing poetry, but not when writing short stories (Baer, 1996). The content of the poetry-related divergent thinking training exercises included:

- * finding words that sound like a given word (rhyme and assonance)
- * finding words that have the same sound as a given word (alliteration)
- * finding words that could stand for or in some way represent a given thing or idea (metaphor)
- * inventing words or descriptions of things that are richly suggestive of other things (images)

The exercises were designed to increase fluency, flexibility, originality, and elaborative skill in each of these areas.

These results are in line with the results of studies that have simply measured creativity across domains. There are strong within-domain correlations, showing that students who show creativity within a domain on one occasion are likely to do so on future occasions. In striking contrast to this within-domain consistency, however, creative performance in one domain tends to be not at all predictive of creative performance in other domains. There are some students who are creative in multiple domains, of course, but no more so than chance would predict. For example, in one especially large study with multiple tasks in each of the two domains assessed (creative writing and art), the 16 within domain correlations were consistently large and statistically significant, but not one of 20 the cross-domain correlations reached statistical significance (Conti et al., 1996).

What does this mean for teaching creativity? The answer is both simple and hard: Teachers must teach creativity in every subject area in which they want to help their students become more creative. Teaching for creativity in drawing, for example, will impact students' creativity in that area in positive ways, but will generally have no impact on their creativity in science, language arts, or other areas. Teachers cannot teach creativity generically; they must teach it, promote it, and nurture it domain by domain.

It should be noted that the question of the degree to which creativity is domain specific is an area of active research. No one doubts that there is a significant domain specific aspect to creativity; the open question is whether there is also a domain general aspect, and, if so, how significant domain generality factors might be. But for those who wish to teach for creativity, there is a simple choice. There can be no loss in assuming even total domain specificity, whereas assuming domain generality takes on considerable risk. This is because even if domain specificity is one hundred percent false, the creativity trainer who assumes domain specificity

will be just as effective as he would be if creativity were entirely domain specific, whereas the trainer who assumes domain generality could (if creativity proves to be largely domain specific, as research increasingly suggests) could be wasting much of her students' time. If creativity is domain general — in which case it wouldn't matter the content of the training exercises the teacher uses — then whether the exercises were drawn from multiple domains (as domain specificity encourages) or all from the same domain would have no influence on the outcome. The result for students would be the same.

But if creativity is domain specific, then the content of the training exercises matters very much. A trainer who assumed domain generality could choose content from any domain, including using all content from just a single domain (as in the [Baer, 1996](#) study described above). This would result in a creativity training effect limited to just that one domain. Therefore, unless one is absolutely certain that creativity is primarily domain general — a conclusion that seems less and less likely to be true — then teachers who wish to develop their student's creativity are well advised to assume domain specificity.

It is important to understand that domain specificity of creativity doesn't mean that multidisciplinary and interdisciplinary thinking and problem solving can't be done. Teachers need to teach for and encourage such thinking. But interdisciplinary thinking and problem solving require both expertise and thinking skills (including creative thinking skills) from multiple domains, each of which must be developed and acquired domain by domain. Creative interdisciplinary thinking and problem solving will require going beyond what one understands and can do in one domain — and often synthesizing ideas, approaches, and techniques from multiple domains — but such thinking is impossible without solid grounding in the content and creative thinking skills of the various domains that one's interdisciplinary efforts hope to bring together.

Intrinsic Motivation

It will surprise no one to learn that people tend to be more creative when they do things they find interesting, personally fulfilling, and meaningful. Teachers hardly need to be convinced that intrinsic motivation is a good thing: there are already so many other reasons that teachers want to promote intrinsic motivation in their students that adding "Boosts Creativity" to the list just seems like icing on the cake. This is surely one way in which teaching creativity fits hand-in-glove with what teachers would want to do anyway.

The intrinsic motivation story quickly becomes complicated, however. Intrinsic motivation competes with extrinsic motivation, and in this competition, extrinsic motivation tends to win. Extrinsic constraints (such as doing things in order to earn a reward or anticipating evaluation of one's work) tend to drive out intrinsic motivation ([Lepper and Greene, 2015](#)). This "hidden cost of reward" means that when teachers offer students rewards (or when they promote extrinsic motivation in other ways) they may be inadvertently undermining intrinsic motivation (See Motivation).

The research of [Amabile \(1983\)](#), [\(1996\)](#) and et al. demonstrated how extrinsic constraints can be detrimental to creativity. In more than a score of experimental studies with participants ranging in age from kindergarten through college, she showed that offering rewards and having students expect that their work will be evaluated tends to decrease their creative performance, and this effect that is especially strong among adolescent girls ([Baer, 1997b, 1998a](#)). There may be conditions under which this effect does not apply ([Eisenberger and Shanock, 2003](#)), but in general the effect is both real and of considerable strength. This presents a significant challenge to teaching creativity.

There are times when teachers can reduce the salience of extrinsic constraints, or even remove them entirely. For example, one can sometimes assign students the task of creating something (e.g., a short story, a poem, or a work of art) with the understanding that it will not be graded or evaluated in any way. For such an assignment students need to do *something*, but as long as they turn in something— anything — they get full credit. Some students will take advantage of this, of course, and do as little as possible, but others will make good use of the freedom that such an assignment gives them. This kind of assignment is sometimes a genuine possibility and should be utilized.

But much of students' work must be evaluated in order for students to learn and develop skills. Feedback of any kind — even positive feedback — counts as evaluation and will negatively impact creativity. This is a cost that cannot be wished away, because without feedback, students cannot acquire and hone the skills they need both for creative and uncreative thinking and problem solving. Teachers can do things to minimize that negative impact, and they can do other things to try to increase students' intrinsic motivation, while at the same time understanding that their actions will necessarily, at times, increase students' extrinsic motivation at the expense of students' intrinsic motivation and creativity.

Although the positive impact of intrinsic motivation on creativity and the negative impact of extrinsic motivation *appear* to be domain general factors influencing creative performance, this is misleading because intrinsic motivation itself is very domain specific. Consider this parallel claim: One could say that practice is a domain general factor in skill development. Yes, but practice playing a trombone won't increase skill in solving differential equations; the two are unrelated activities, and the fact that one needs to practice both to develop skill is an almost trivial similarity. In the same way, intrinsic motivation to write poetry and intrinsic motivation to do woodworking are unrelated motivations, and having one of the two kinds of intrinsic motivation will affect creativity only in that domain. In both the case of intrinsic motivation and the case of practice, the suggestion that these are domain general factors is true only in the most superficial way. What is important is the content, whether one is talking about intrinsic motivation or practice. Students aren't uniformly intrinsically or extrinsically motivated; they find some activities highly interesting and meaningful and others less so. Increasing intrinsic motivation for studying history cannot be expected to have any impact on

intrinsic motivation to understand algebra (or vice versa). As with teaching divergent thinking, teachers need to promote intrinsic motivation in many different domains.

Teaching for Creativity and Teaching Content Knowledge

Most teachers want to help their students become more creative thinkers. They also want to help students acquire content knowledge and skills of many kinds. Sometimes it can seem as if these two kinds of goals — creativity and content — may be in opposition, especially in an era of teacher accountability. This apparent conflict is, however, in many ways an illusion.

There are indeed areas in which the two goals can sometimes conflict, as has already been noted in the previous section: extrinsic constraints are often needed and helpful in promoting the acquisition of content knowledge and skills, whereas extrinsic motivation often has a negative impact on creative performance. There are also the time constraints of schooling: there is simply not enough time to do everything, and many teachers see teaching for creativity taking time away from teaching things (such as those outlined in the Common Core State Standards) that will be tested.

But that is just part of the story. Creativity and content knowledge — and teaching for creativity and teaching content knowledge — are also mutually supportive in many ways. Creativity requires both content knowledge as well as many kinds of basic skills (e.g., one cannot be a creative historian without knowing a lot of historical content, or a creative mathematician with first acquiring a great deal of mathematical skill). And two of the best ways to acquire content knowledge and develop skills are by thinking about that content knowledge deeply and creatively and by employing those skills in solving real problems.

The possible conflict between teaching for creativity and teaching for content is part of a long-standing dispute about how learning content and learning to think effectively might be related. It should be clear, however, that both critical and creative thinking rely heavily on knowledge. Failures in critical thinking are often the result of faulty premises, and failures in creative thinking are often similarly the result of a lack of domain-specific knowledge. Both critical thinking and creative thinking are supported when students learn the concepts, facts, and skills that make up a rigorous curriculum like the Common Core State Standards. The development of creative thinking therefore requires a strong content-based curriculum.

Content knowledge is of course extremely domain specific. The fact that creativity in most domains requires significant amounts of domain specific content knowledge is no more evidence of a domain general factor than the fact that skill development requires practice is evidence of a domain general factor, as discussed in the [Intrinsic Motivation](#) section. In each case the relevant knowledge or skill is very domain specific.

Looking at the supposed conflict between teaching for creativity and teaching for content knowledge from the opposite perspective, what can teaching for creativity do to promote the kinds of skills and knowledge required of the Common Core (or other curricula)? One of the most effective ways to learn content knowledge is to think about that content in some way — to become actively engaged with the concepts, understandings, facts, skills, or whatever content one wishes to learn. Learning requires that students create meaning — that they construct knowledge — based on their experiences and how they make sense of those experiences. The important kind of engagement with content is active *cognitive* engagement, such as that of creative or critical thinking. Meaningful learning is more effective and more long-lasting than rote memorization of poorly understood or totally uncomprehended facts. And although thinking creatively about content isn't the only possible kind of meaningful cognitive engagement, it is one of the most powerful. There is therefore more potential synergy between teaching for creativity and teaching for content knowledge than there is opposition ([Beghetto et al., 2015](#)).

Teams

Teams are groups of individuals who work together to accomplish a task or series of tasks. Many tasks are accomplished by ad hoc teams brought together temporarily to accomplish a task in a specified period of time such as committees or task forces. Other teams are part of organizations and work together over an extended period of time on a variety of related tasks. One of the key characteristics is that teams are interdependent – that is team members depend on one another for the successful completion of their goals. This often presumes that team members vary in their expertise and have to effectively coordinate their activities to optimize their performance of tasks including creativity tasks. Although teams are often embedded in organizations and may have a history of working together, much research on creative teams and groups involves interactions on specific tasks during limited periods of time in laboratory settings. This research is similar in scope to that done under the label of group creativity. Studies of longer term creative teams are often in the form of case studies. Much of the research on team creativity involves the use of self-report measures of the processes and the outcomes. This is potentially problematic in that the use of such a methodology may not reflect what is actually occurring in teams. Studies of work teams in organizations that use objective measures are relatively rare. Most studies using objective measures of creativity involve laboratory studies of group creativity. Of course, these laboratory studies may have limited applicability to the understanding of creativity in long-term and specialized teams. However, there is considerable overlap in the findings on innovation in work teams and creativity in laboratory groups. Thus, the results from both areas of study appear relevant to understanding the creativity of teams.

Creativity Versus Innovation

The literature on creativity in teams tends to use the term innovation rather than creativity. This may in part reflect a bias in terminology by researchers in organizational behavior who are trying to appeal to the business world. The world of business and industry is interested in innovation or the development of new products or services that are useful and have a positive economic impact. Just because a product or idea is creative does not mean it is going to be useful. So the criteria of usefulness and feasibility are important ones. However, innovation is also often reserved for implementation of ideas generated during a prior creative

[☆] *Change History:* September 2019. Paul Paulus updated the text throughout the article.

This article is an update of P.B. Paulus, N. Kohn, M. Dzindolet, Teams, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 446–452.

phase. Creativity is seen as an exploration phase of generating novel alternatives or solutions, and innovation as a phase of exploiting the ideas toward some useful end. Although it is presumed that different principles govern the different phases, the literature suggests that many of the same factors that influence creativity also influence innovation. Successful exploitation or implementation of ideas also requires creative thinking. This thinking may not be as radical or divergent as that in a prior exploration phase but is creative nonetheless. Moreover, in many studies of team innovation, there is not a clear distinction between the processes of exploration (the initial generation of a range of ideas) and exploitation (selection and development). Thus this summary of team creativity literature will ignore the innovation/creativity distinction, except in the discussion of the phases of the creative process.

Basic Processes

Team creativity involves social interaction and collaboration. That is, team members engage in a variety of social activities in order to complete their tasks. In the early stages they may have discussions about goals, task distribution, coordination, feedback systems, and compensation. If they are involved in a creative task there is at some point a process of sharing ideas about a particular issue or problem. This may be followed by some evaluation of the different ideas and possible implementation of the most promising ideas. These processes may be repeated in different sequences during the life of the team. The focus of this entry is on the creative or ideational phases of the team process since there is a significant literature on this issue. The initial planning and later innovation stages may involve somewhat different processes.

Theories of collaborative creativity have recognized both the social and cognitive forces that play a role. Some theories have emphasized the cognitive aspects of collective ideation. As individuals share ideas they need to search their memory or knowledge base for relevant information or ideas. When these ideas are shared in a team, they may stimulate others to think about related issues. So collective sharing of ideas should increase the range of topics or issues that are discussed and lead to mutual stimulation of ideas. Of course this requires careful attention to the shared ideas and thoughtful relating of these ideas to the knowledge or memory base of each team member. This may be facilitated by some intermittent opportunities to reflect on the shared information.

At the same time, the idea sharing process may provide a social stimulus for increased effort as team members compete in trying to come up with more and better ideas. This would be particularly true if there is some degree to which individual group member contributions can be identified and recognized. It also appears important that team members function effectively to seek help and give help at critical times in the creative process. This process needs to be reinforced by positive experiences in the group and a supportive organizational culture. However, the social context can also hinder the creative process because of concern about deviating from normative group expectations and there may be a tendency for group members to focus on areas of agreement rather than their potentially unique perspectives. A fundamental process in team creativity is the communication among team members and with other teams. This process appears to be strongly related to team creativity, although there is some evidence that too much communication can be detrimental. A high level of communication may distract from one's focus on the task or may involve task-irrelevant as well as task-relevant information. Irrelevant information may make it more difficult to focus on the essential aspects of the task. A key task for creative teams is to process the shared ideas, elaborate on them, and integrate them into a high quality innovation. This requires effective integration of the diverse knowledge bases present in the team.

Factors Influencing Team Creativity

Much of the research on team creativity has examined the factors that influence the degree to which teams, especially work teams, develop creative ideas, or innovations. The basic presumption is that the composition of the team, the characteristics of the team members, and the task and social context of the team will influence these outcomes. This presumption is consistent with an input–process–output perspective of teamwork. This perspective focuses on the person, team, and context characteristics that influence the team processes that in turn affect the various outcomes such as performance, satisfaction, and team viability. This framework provides a useful means for organizing the presentation of the major findings. This entry will summarize the major factors that influence the team processes and the resultant degree of creativity.

Team Member Characteristics

To a large extent the innovativeness of a team depends on the personal characteristics of the team members. The higher the creative ability of the individual members, the higher will be the creativity of the team. Teams whose members who are open to new experiences, extraverted, have a promotion focus (oriented to achievement rather than safety), and have an ability for divergent thinking are more likely to be creative. It also is beneficial if team members have a positive attitude toward the team. High levels of collective creative self-efficacy also seem to be related to higher levels of team creativity. Such team level self-efficacy likely requires prior shared experiences of creative success, and so teams that already have a composition that is favorable for creativity are likely to develop increased confidence in their creative ability, further enhancing their creative output. The teamwork literature suggests

that it is important for team members to have a range of team-relevant skills such as shared leadership, coordination, performance monitoring, and adaptability.

Although having more members with certain personal characteristics increases the potential creativity of the team, it may also be beneficial to have a mixture of team members with somewhat different characteristics. This may be particularly important as the team goes through different phases of the creative process. During initial divergent ideation sessions, having group members who are able to come up with a lot of creative ideas will be beneficial. However, in later idea development, elaboration, and implementation phases, group members who are motivated to persist in the difficult task of coming up with a solution that deals with various technical, financial, and social constraints may be most impactful. Group members who are high in conscientiousness, agreeableness and prevention focus (concerned with attaining security and avoiding loss or harm) may play critical roles in these later phases. The impact of team composition also depends on a variety of group-level and contextual factors such as variation in status level of team members, degree of group interdependence and the extent to which the context allows for or constrains the full expression of individual differences.

Team Size

Teams can vary greatly in their size, depending in part on their scope and the complexity of their task. Complex and multifaceted problems may require a wide variety of expertise on the team. Since larger teams are more likely to consist of members with diverse perspectives and skills, it is not surprising that larger teams are associated with more innovation. However, large teams may also have drawbacks since they may reduce the extent to which individual members feel accountable or important to the rest of the team. Thus there may be some loss of individual motivation. Moreover, in large team meetings it may be difficult for all team members to effectively contribute because they have to share the available discussion time. It appears that the ability to express one's ideas as they occur is important in one's ability to generate a flow of ideas. This interference effect due to having to coordinate the expression of one's ideas in the group is known as production blocking. Therefore, it may be best to keep the team as small as possible while still providing the range of expertise needed.

Diversity

One of the benefits of bringing team members together on a creative task is to take advantage of their diversity. Diversity represents the variation in personal characteristics of team members. Team members can vary in their demographic characteristics such as race, gender, age, tenure in the organization, personality, status, values or beliefs, knowledge, experience, and expertise. Each of these characteristics may make interacting with other team members interesting, but research has found that most people prefer to interact with people who are similar to themselves. So there may be a social bias to homogeneous groups or teams. In diverse groups, group members may be somewhat uncomfortable in sharing their ideas or perspectives since they may conflict with those of other group members. Groups often like to gain a consensus based on common perspectives, as seen in cases of groupthink in decision-making groups. So individuals in groups may be more responsive to an idea which is familiar rather than one that is different or unique. As a result most reviews of the literature have found that overall diversity is not related to enhanced performance in groups or teams.

Diversity in knowledge or expertise (functional diversity) does appear to be related to enhanced team creativity. The effects for demographic diversity are more inconsistent. Effective tapping of this type of diversity requires that group members have a positive disposition or attitude to interacting in diverse groups and that they are either intrinsically or extrinsically motivated to take advantage of the diverse ideas or information shared by the team. Intrinsic motivation requires a strong personal interest in the creative activity and learning from others. Extrinsic motivation involves social or organizational incentives (such as financial incentives or prizes) that motivate team members to work hard. Under such conditions team members may carefully process or elaborate the shared ideas and information and come up with potentially innovative ideas based on the diversity of perspectives present in the group. However, demographic or value diversity may not have much influence on creativity unless it is relevant to the team task. Thus the development of an advertising campaign for diverse populations may benefit from demographic diversity, but this type of diversity might not have a positive influence on the development of some innovation in healthcare or technology. This type of innovation will probably require people with diverse expertise or experience relevant to that issue.

Interdisciplinary Teams

The research on diversity suggests that interdisciplinary teams should be helpful to creativity. Interdisciplinary teams consist of individuals who are experts in different areas relevant to some task or goal. In science this may involve scholars from different disciplines, in technical fields they may consist of people with different technological expertise, and in work settings they may involve employees from different departments or divisions. The presumption is that for broad problems or initiatives, a broad range of expertise or knowledge will be required. Teams that include individuals that represent these divergent perspectives or areas of expertise will be better able to solve complex problems or come up with creative solutions or ideas. One can make a distinction between multidisciplinary and interdisciplinary teams. Multidisciplinary teams involve team members from different disciplines coordinating their efforts to achieve a common goal. This type of collaboration primarily involves the use of complementary areas of expertise required to accomplish a goal. Interdisciplinary teams require a higher level of collaborative interaction that involves the

actual integration of knowledge or expertise to create new concepts, theories, techniques, or approaches that go beyond what was possible in any one of these disciplines alone. Members of interdisciplinary teams have to effectively coordinate their various contributions to achieve the group goal. They also need to understand each others' areas, and this level of enhanced mutual understanding may allow the team to reach new levels of technical development.

Achieving mutual understanding in interdisciplinary groups may be difficult. Groups tend to focus on areas that they have in common, in part because such common understandings have obvious validity to the team members and provide a sense of cohesion. It may be difficult for team members to understand each other's unique areas of expertise unless they have broad training or expertise. With the increasing specialization in all areas of science and technology, few have the time or inclination to develop the broad expertise to effectively understand and build on diverse areas. However, it may be sufficient if team members have the basic knowledge to understand the exchanged communications. An important issue for future research is to determine the role of depth and breadth of expertise in the creative potential of interdisciplinary teams.

Interdisciplinary teams appear to function best when the context or relationships among team members enhances the communication processes. So teams whose members are located close to each other physically or who are in the same organization tend to be more effective than those who are at different locations. Also, it appears to be beneficial if the team members have some degree of collaborative 'closeness' in that they communicate frequently and have strong interpersonal bonds. This is most likely to occur if team members have considerable experience in working together effectively. In fact, the team members who are at the center of the information flow and are aware of the distribution of expertise in the team tend to perform best. Smaller interdisciplinary teams seem to be more innovative than large ones, presumably in part related to more effective information exchange in the smaller teams.

Team Experience Versus Turnover

Teams that have spent some time working together are likely to function more effectively than those that do not have such experience. Such teams can develop shared mental models (common understandings among team members about team composition, goals, and tasks), learn who knows what (transactive memory) and how the team will work together to accomplish its goals. Such teams may also develop the ability to reflect on their processes and make appropriate adjustments (reflexivity). However, in most teams members change periodically. Loss of members who have key skills or knowledge can be very detrimental to the functioning of the team. The team can also lose some of its cohesion and may have to redevelop its transactive memory systems. Although research on the issue of turnover in teams is limited, there is some research indicating that periodic changes in group members can enhance creativity. The new perspectives provided by a new member could stimulate other team members to think more deeply about issues or reevaluate their ideas. However, in reality this effect will also depend on whether this team member is a creative person who asserts him or herself effectively as a new member of the group. Newcomers in groups may have to first establish social ties with other group members and adopt the group norms before they can begin to have an innovative impact on the other group members. The impact of contributions by newcomers to the team is also enhanced if they share a common identity with the group (i.e., they share a common goal, values or personal characteristics). However, this positive effect may only occur if the newcomer makes high quality contributions.

Conflict

When team members share diverse perspectives, there may be conflicts. Conflicts in teams are generally associated with negative feelings, especially if the conflicts are social in nature. However, it appears that cognitive conflicts that involve differences in perspectives can stimulate creativity. Such conflicts can lead participants to reevaluate their own perspectives, especially if those presenting the conflicting perspectives are persistent and do so in a way that is not offensive to the team. In fact, exposure to conflicting perspectives may increase the tendency to divergent thinking and affect creativity on tasks totally unrelated to the setting in which the conflict was experienced. Apparently, the experience of divergent perspectives increases the extent to which a person is willing to consider alternative perspectives in general. Even though cognitive conflicts can increase creativity among group members, overall performance of the group may not increase. Cognitive conflicts may have negative emotional effects which can inhibit the types of interactions required for the overall effective performance of the team. Thus it is not surprising that a number of studies have found that moderate levels of conflict may be optimal for team creativity. However, it is also important for groups to have a collaborative atmosphere and feelings of interpersonal trust or psychological safety. This may require team leadership that helps teams to develop these characteristics.

Team Climate: Safety and Cohesion

It is important for teams to have a positive orientation toward creativity. That is, they share positive beliefs, expectations and norms about innovation. One of the key factors in fostering a creative atmosphere in a team is psychological safety. This is the extent to which group members feel that they can express their thoughts and ideas without fear of negative reactions from their fellow team

members or the organizational leadership. When participants have this kind of feeling, they are more likely to share their unique and possibly controversial ideas. However, some reviews of the literature suggest that psychological safety may be a somewhat weak predictor of innovation. This may be in part because it needs to be balanced with appropriate levels of accountability. In an 'anything goes' environment team members may be tempted to loaf and may drift in their task focus. Some degree of task structure and specific goals may be needed to keep team members on track. Some time or task constraints, requirements or goals may help motivate higher levels of team creativity in psychologically safe contexts.

In a similar vein, research has found when there is an element of trust among the participants involved in a creative enterprise, creativity is more likely to flourish. Trust represents the feelings that others care about one's well-being and one can count on their support even for the 'risky' activities that may be involved in creative work. In fact, the emotional support for one's creative activities from both fellow workers and from family and friends are important for enhancing creative performance. So team members need to trust one another and to support one another in their creative activities. This does not mean that all the innovative ideas expressed have to be accepted or carried out. However, team members should feel that their creative ideas will get a fair hearing from the team.

Another important source of support is the organization within which the team is embedded. Unless the organization and its leaders support creative activities by the team, the team will not have an incentive to be creative and will not feel comfortable in sharing novel ideas for improving the organization and its various projects. A psychologically safe environment may lead to positive interpersonal feelings that are an important component of group cohesion. Group cohesion is the extent to which group members are attracted to the group and its goals. Cohesion can consist of feelings of interpersonal liking, task commitment, and group pride. Not surprisingly these factors have been associated with enhanced performance in groups and teams. Cohesion should enhance creativity since team members feel comfortable with one another and are motivated to achieve the team goals. They should not be inhibited in sharing their unique perspectives and should work hard to integrate these perspectives to come up with a novel solution. Cohesion may take some time to develop, so positive effects may not be evident until the team has been together for a period of time. However, long-term teams that are cohesive may not necessarily be optimal for creativity. There may be pressure to maintain the positive team feelings and to act in accord with the group norms or expectations. This may inhibit the sharing of novel perspectives that are contrary to the dominant views of the team. In these settings it becomes even more important to insure openness to diverse or contrary perspectives or psychological safety. It may also be important to balance team cohesion with some degree of membership turnover and active contacts with experts outside the team.

Task Structure

Creativity is generally seen as an unstructured activity in that the participant should be as unconstrained as possible by reality, task structure, and time. There is in fact considerable evidence that periods of time without distractions or other demands can facilitate creative achievements. This is particularly true for individuals who have a strong intrinsic motivation for their creative pursuits. Research indicates that it is important for such individuals to have a high degree of autonomy or freedom in their task activities. Increasing task constraints and applying external pressure for task achievement may in fact reduce such intrinsic motivation and creativity. Autonomy also tends to be important for teamwork. Much research has shown that teams that are self-managing, in that they have a choice in their tasks, task processes, and team procedures, tend to function better than those that do not have such autonomy. Similarly, team autonomy appears to be related to enhanced creativity.

Although autonomy and freedom appear to be important for creativity, some degree of structure may also be helpful. It helps to have clear goals and objectives. The team can collaborate in setting such goals, but there may be some tendency to set 'attainable' goals rather than challenging goals to avoid the experience of failure. It should also be clear that the goals are for creative production. If the organizational context provides psychological safety, group members may feel it is 'safe' to select ambitious goals. These goals can vary in the extent to which they emphasize originality and feasibility or applicability. Although mutual goals of innovation and feasibility can be seen as conflicting, some research indicates that such dual goals can in fact be quite effective in promoting both originality and the generation of feasible products or ideas.

Although external pressures or incentives can reduce creative motivation, this is not inevitably the case. When these external forces are seen as external control, it may lead to reduced intrinsic motivation. However, when the external forces are perceived as confirming one's competence or enabling one to do an intrinsically interesting task, they may actually increase overall motivation. Competition within the team or with other teams may be one such external motivator. Performance feedback or the provision of challenging goals may have similar positive effects on the creative production of teams. In addition to having some 'directive' social contexts, the task context is also important. In particular it appears that it is useful to have some degree of task structure. Breaking a task into its subcomponents, explicitly defining the problem, providing brief breaks during long idea generation sessions, and providing clear instructions about how to efficiently share are important in increasing the number of ideas generated.

Therefore, in order to increase team creativity, intrinsically motivated group members should be given a high degree of autonomy and time to perform the task without distraction. The development or provision of clear, challenging but attainable goals, performance feedback, and intra- and intergroup competition can increase motivation without decreasing intrinsic motivation. Although many see creativity as an unstructured activity, certain procedural guidelines can improve team creativity.

Training

Although there is considerable research on training creativity and training teams, there is very little systematic research on the training of group or team creativity. While experience in creative groups may be beneficial, it may also lead to the development of task procedures which are not beneficial to enhancing team creativity (such as the amount of time spent in group interaction). Although the creative process in a particular team may appear to be quite successful, team members typically do not have a clear basis for assessing how effective they have been. Research that used control groups as a reference point found that providing groups training that includes practice and the reinforcement of efficient sharing strategies increased the quality of ideas generated.

Leadership

It is typically presumed that groups need leaders for effective performance. There is a massive literature on leadership in general and considerable data on leadership for groups. Group leaders may be external such as bosses who assign tasks to teams. Teams may also have internal leaders who are actually members of the group. These leaders may be assigned, elected, or may simply self-select to this position in the absence of any clear structure. In general, it appears that team creativity can be enhanced by leaders that provide a clear vision or goals, provide support for innovative activities, and develop a climate in which team members feel it is safe to explore creative directions. Therefore it is not surprising that some studies found that a transformational leadership style that involves providing individual mentoring, encourages challenging old assumptions, and inspires sharing their vision and setting high expectations is sometimes related to team creativity. However, it also appears that both task oriented leadership (structuring the task, setting goals, directing interaction) and relationship or participative oriented leadership (concerned with good relations and encouraging personal initiative) can enhance team innovation. Participative leadership may be most helpful in the early idea generation stages of the innovation process while the task oriented leadership may be more helpful in the implementation phase. Similarly, there is evidence that ambidextrous leaders who are able to vary their interactions with the team to align with the needs of the different phases are optimal for team innovation. It may also be useful to have a shared leadership in which leadership changes depending on the phase of the process (exploration or exploitation) or the type of expertise needed as in the case of interdisciplinary teams.

Teams may also exercise 'self-leadership' if they have considerable autonomy. Such leadership may take the form of shared leadership with different members leading different aspects or phases of the task. Such shared leadership requires effective skills in knowing how to allocate task components and when to switch leaders. Teams will need some extensive experience or training to develop such adaptive routines. This may involve 'coaching' group members to optimize motivation, task allocation, and appropriate alignment of task routines with task requirements.

Interteam Creativity

Many teams work in organizational contexts in which they interact with other teams. Such interaction can enhance creativity both at the level of the teams and the organization. Exchange of ideas among teams may enhance their creative potential by increasing the diversity of perspectives. If there is some degree of competition among the teams for the development of innovations, team members may make greater efforts to excel in their creative efforts. However, there are also a number of factors that limit interteam creativity. There may be strong in-group biases which may limit the extent to which group members exchange ideas and build on such 'outside' ideas. An important factor in facilitating interteam creativity is the extent to which there exist communication networks among the members of different teams. This is particularly true when there are knowledge gaps or structural holes among the teams. When teams have non-overlapping knowledge bases there is likely to be a greater benefit of exchange of ideas among the teams. However, it is important for team members to be receptive to such information and overcome their intergroup biases. In the broader teams literature there has been much focus on multi-team systems which require coordination among different teams in organizations. This research also discovered many factors that inhibit effective coordination among teams. Even when these teams have shared goals, the inhibiting factors can still play a role. Effective interteam processes will likely require effective leadership and team training.

Electronic Creativity

With the increased availability of digital means of communication such as email, cell phones, computer networks, and the internet, there is much potential for creative collaboration by electronic means. If group creativity is construed primarily as a process of mutual cognitive stimulation, electronic communication should be as effective as face-to-face communication. In fact, research on electronic brainstorming, in which participants share ideas by means of various group information sharing systems, has found that electronic exchange of ideas can be more effective than face-to-face exchanges, particularly for large groups. This may reflect the fact that electronic exchanges avoid the production blocking inherent in face-to-face settings. One potential disadvantage of electronic exchanges is that it may be more difficult to build cohesion when the interacting members are working from distant locations.

Interpersonal ties may be important in motivating interactions among group members and may facilitate understanding of each other's ideas. Electronic interactions also vary in the richness of interaction modalities. Some may be limited to written exchanges of information while others may involve visual and auditory interactions through the use of video technology. Richer technologies may allow for more effective communication of meanings since they provide for the exchange of various linguistic and paralinguistic cues.

Summary

Team creativity is influenced by a range of cognitive and social factors. Team members need to be highly motivated and to carefully process the shared information or ideas in order to develop creative products. Teams need both autonomy and some degree of structure and goals to function at a high level. A psychologically safe environment, participative or transformational leadership, and training appear to facilitate creative team performance. Diversity, conflict, and turnover of membership can both facilitate and hinder creativity. Electronic exchanges of ideas among team members can be quite effective.

There is no simple recipe for creative teamwork. Many of the factors discussed in this entry can have both positive and negative effects depending on their level or other factors. In general there seems to be support for a sort of 'balance' perspective. Teams should be large enough to do the job, but as small as possible. Some degree of diversity, conflict, and turnover can increase creativity, but too much will backfire. Psychological safety and cohesion are important, but too much may make the team members too comfortable with the *status quo*. A high degree of autonomy may motivate creativity in teams, but without some degree of structure, external goals and effective leadership, the team may not accomplish much. Some degree of virtual interaction among team members may facilitate the exchange of information and ideas, but face-to-face sessions may be needed to deal with more complex problem solving and decision aspects of the creative process. So organizations that foster teams will need to be sensitive to balancing these various dimensions to optimize the creative performance of their teams.

The Agenda of Computational Creativity

When Herbert Simon wrote to George Miller on April 30, 1957 claiming that creativity was no longer “as mysterious and inexplicable” as some made out (Herbert Simon Papers, Carnegie Mellon University Archives, Pittsburgh, Pennsylvania), he was riding the wave of success he and Allen Newell had achieved with their computer program Logic Theorist (LT) (Newell and Simon, 1972) which marked the proper beginning of artificial intelligence (AI). A few years later Simon and his co-investigators went on to suggest that human creativity is a kind of computational phenomenon (Newell et al., 1962). This belief, that computational models offer a means of explicating creativity, was an early expression of what, decades later, Jeanette Wing (2006) would call *computational thinking*: the idea that understanding human behavior can be influenced by comprehension of the behavior of computational artifacts. In claiming that human creativity is a computational phenomenon, Newell et al. were indulging in a quintessential form of computational thinking.

Of course, this begs the question: If computational modeling of creative processes could help us understand human creativity, then what is to be the foundation, the inspirational source, for constructing computational models? The only option is human creativity itself, for that is all we have to go on: any discussion of creativity, whether of humans, animals or machines is inevitably and ultimately anthropocentric. This suggests a kind of iterative situation in which human thinking about creativity influences computational modeling of creativity which in turn influences (and presumably enhances) the understanding of human creativity.

Computational thinking about creativity, thus has two distinct faces: on one side, is the problem of constructing computational artifacts (or systems) that manifest creativity (in some sense); on the other, is the problem of eliciting insight into human creativity from such computational models. In recent years the first project has come to be called *computational creativity* — which is the topic of the present article; but as noted, the issue of human creativity can hardly be avoided.

The agenda of computational creativity is a direct derivative of the agenda of AI. The broadly accepted view is that AI's concern is the study and construction of computational systems that exhibit behavior that would be deemed ‘intelligent’ if performed by human beings. Likewise, the concern of computational creativity, broadly stated, is the study and construction of computational artifacts that exhibit behavior which would be deemed ‘creative’ if manifested by human beings (Lamb et al., 2018).

This immediately raises two questions: What is considered to be ‘creative behavior’? And who decides ?

Creativity as History Making

As many creativity researchers have noted (see, e.g., Buchanan, 2001), there is much ambiguity and disagreement about what it means to be creative. The first task at hand, then, is to abstract from these multiple perceptions of creativity and capture in some reasonably uncontroversial fashion the *intuitive* idea of creativity.

Before proceeding with this task two useful terms need to be introduced. First, the term *artifact* will refer to any non-natural thing. This may be material (e.g., a sculpture, a building, or a scientific instrument), abstract (e.g., a mathematical theorem, a design or a philosophical idea) or hybrid (e.g., software). Second, the term *artificer* will mean the producer of an artifact. In the realm of human creativity artificers are, of course, persons, while in the context of computational creativity artificers happen to be artifacts.

Armed with these terms the following is proposed: *To be creative is to make history*. More precisely, an artificer is creative if, in producing an artifact she (or it) makes history.

This *historicalist* perspective originated with Margaret Boden (1991) who identified two kinds of history-making. One is when an artificer produces an artifact that is original with reference to the artificer's *personal* history. Boden called this *P*-creativity (*P* for

personal or psychological). Others may have created the same artifact before but this does not dilute the artificer's personal cognitive achievement.

Boden's second kind of history-making, which she called *H*-creativity ('H' for historical) is when the artificer produces an artifact that is original with respect to *all* of past history, that is, with respect to all of time preceding the time when the artifact was created.

But the artifact's originality must not be conflated with mere novelty. The artifact must be valuable or significant in some sense. In the realm of *P*-creativity this significance may arise because of the difficulty of the problem which gave rise to the artifact. In the realm of *H*-creativity, an artifact's value or significance may lie in its surprisingness; or because the artifact resolves a long-held dilemma; or because it falsifies a current theory or belief; or, most significantly, it is perceived to have *consequences* that may shape or have shaped the future history of the relevant domain.

This last situation, referring as it does to future time, suggests a historicity distinct from the realm of *H*-creativity. The present writer (Dasgupta, 2019, pp 28–31) referred to this as *C*-creativity ('C' for consequential). This is manifested if one can discern an epistemic connection between the artifact so produced (say at some point of historical time *T*) and one or more artifacts produced at some later time *T'*. That is, the knowledge embedded in the earlier artifact serves, at least in part as an input to the production of later artifacts. As two examples consider Picasso's painting *Demoiselles d'Avignon* (2007) which gave rise to Cubism, a painterly style (an abstract artifact), and the invention of the stored program computer concept (an abstract artifact) in 1945 created by John von Neumann and others, the principles of which would be incorporated not only in the first digital electronic stored program computers (material artifacts) implemented in 1949 but also in virtually every other physical computer since.

But there is another marker of originality in the historicist sense. An artifact is produced at some point of time *T* and it is discovered at some (possibly *much*) later time *T'* that an artifact was created bearing a marked similarity to the earlier artifact, though there may be no evidence of an epistemic connection between the two. This has been referred (by the present writer) as *A*-creativity ('A' for anticipatory) (Dasgupta, 2019, p. 30). Perhaps the most interesting example of this is Charles Babbage's design of the Analytical Engine in the mid-19th century which anticipated by almost a hundred years, the stored program computer concept.

So the historicist proposition leads to four kinds of creativity: Boden's well known *P*- and *H*- varieties, and the more recently identified *C*- and *A*- varieties.

The Judgement of Creativity

Consider now the second question raised in [section The Agenda of Computational Creativity](#): who decides an artificer to have been creative? It needs to be recognized that for every act of creation there will also be a *consumer* of the produced artifact: a fellow scientist, a fellow artist or a connoisseur, a literary critic, an informed user and so on. The consumer may be contemporaneous with the artificer or at a temporal distance — perhaps decades or even centuries later. The consumer may also serve as the *judge*. In certain domains, such as the sciences, the only kind of consumer who can serve as a reliable judge is one who possesses the knowledge, training, expertise and intuition to make responsible judgement. Such a judge may be called a *peer consumer*. Other domains, in addition to peer consumer-judges, may also have *lay consumers* who also judge — e.g., the 'ordinary' literary reader, the art or music lover, the film watcher, etc.

So here is the scenario that emerges. First, the unit of creativity is a triplet: <artificer/artifact/consumer>. Just as there is no creativity without the artifact or the artificer, there is no creativity without the consumer. Second, there is no objective criterion whereby creativity can be determined. It is, instead, a matter of subjective judgement, where the judge may be the artificer herself or more usually a consumer. The situation may be formulated in the following manner:

There is an artificer who brings into existence an artifact. This 'act of production' becomes an 'act of creation' when (and only when) the artifact is judged by one or more consumers to be significantly original in the *P*-, *H*-, *C*-, or *A*- sense. The artificer is accordingly judged to be *P*-, *H*-, *C*- or *A*-creative.

Here, note that a distinction is made between originality and creativity: the former refers to the artifact and the latter to the artificer. This scenario also implies that because of the subjectivity of its judgement, what might seem to be a case of creativity to one consumer-judge might not be so to another. Picasso's *Les Demoiselles d'Avignon* was rejected by some of the artist's closest friends when they witnessed it as work-in progress in 1907. In the eyes of these particular peer consumers — all possessing considerable expertise and sensibility in matters of art — the painting was judged novel but not valuable, thus not an expression of creativity. Ten years later, however, a different judge, pioneer of surrealism André Breton judged it very differently, and in 1937 Alfred Barr, then director of New York's Museum of Modern Art proclaimed the work as arguably the most important painting of the 20th century.

The Artificer as a Purposive Being

There is yet another essential aspect of human creativity that must be noted: an act of production begins in a *goal* or *need* generated in an artificer's mind. For example, a scientist feels the need to satisfy his curiosity about some newly observed natural phenomenon; a poet desires to respond to a felt emotion; an inventor, dissatisfied by the performance of a particular machine feels the need to improve its design; a novelist desires to capture her childhood by writing a story.

Thus, the creative artificer is a purposive being; creativity is a purposive phenomenon. Perhaps the supreme and most universal desire manifested by creative artificers is that they wish to deviate from the norm; to *be* original. One may think of this as

a ‘superneed’ without which no act of creation can even begin. But there are lesser though still compelling needs, such as the writer’s need to write, the painter’s need to paint, the scientist’s need to explain, the inventor’s need to invent, and so on.

The Artificer’s (and Consumer’s) Discourse Space

The artificer is not an island of her own. As noted she needs consumers, preferably a *society* of consumers. Consumers may serve as judges but they also serve as agents of transmission of the created artifact to other members of their society, or even to other societies. This is one of the means by which C-creativity obtains.

More generally, the human artificer plies her trade in what may be called her particular *discourse space*. The society of consumers constitute one component of this space; so does culture — the matrix of customs, traditions, manners and mores, symbol structures, knowledge and beliefs, values, perceptions, language, art objects, utilitarian objects, and world views, the *artifactual world* — she is embedded in, has inherited from outside her skin. Collectively, society and culture constitute the *environmental* part of the artificer’s discourse space.

There is also, of course, the *cognitive* part, which resides within the artificer, containing structures of beliefs and knowledge, affects (emotions), needs/goals (including supersedes) and a repertoire of mental operations.

The artificer, thus, posed by a particular situation — derived from her discourse space — experiences a need or desire which leads to her constructing a goal in response; drawing on elements of her discourse space she constructs a cognitive process (out of her repertoire of mental operations which may direct physical actions) that produces an artifact in response. Collectively, this process constitutes the artificer’s act of production.

Whether this artifact is original or not and whether in producing it the artificer manifests creativity, is judged by one or more consumers from the artificer’s environmental subspace; the latter in turn may appeal to *their* respective discourse spaces in order to make this judgement and to judge the nature of this creativity — whether it is of the P-, H-, C- or A- variety.

The Challenges for Computational Creativity

There is much more to this model of the human act of creation which for lack of (textual) space we must omit. For instance there is the thorny problem of the role of the unconscious in the act of production; the role played by mental schemas in creativity; and the fact that human creativity involves a sense of the past — a historical consciousness or sensibility — in the relevant domain of creation. (These and other relevant matters are discussed at some length in [Dasgupta, 2019](#).) But this model, as briefly stated, suffices to make sense of the challenges posed to computational creativity research.

If the goal of computational creativity is the theory and practice of how artificers *that are themselves computational artifacts* may manifest creative behavior as perceived by human beings (see [section The Agenda of Computational Creativity](#)) then it is human creativity and its production that sets the bar of acceptability: to what extent and how does such a computational act of creation manifest characteristics of the human act of creation? Herein lies the first challenge for computational creativity. [Colton and Wiggins \(2016\)](#) frame this challenge in terms of the extent to which computational systems may take on the “creative responsibilities” normally manifested by human artificers. In fact, as the literature indicates, it is the judgement of creativity — the act of consumption — that emerges as the lodestone for assessing progress in computational creativity research rather than the actual act of production itself ([Lamb et al., 2018](#)).

One of the most impressive early projects in computational creativity was the work by Pat Langley and his collaborators in the mid-1980s (summarized in [Dasgupta, 2019](#)). They took up the challenge of building computer programs that would ‘re-discover’ some of the classical quantitative and qualitative laws of physics and chemistry.

One of these programs, called BACON.1 ‘discovered’ several versions of Kepler’s third law of planetary motion. BACON.1 was a heuristic program which employed a repertoire of heuristic rules, some of which were used to gather data (by requesting them from the user), others that served to detect regularities in the gathered data, and still others that inferred ‘higher level’ patterns from these regularities including, ultimately, Kepler’s third law.

In fact, a scrutiny of BACON.1’s discourse space reveals that it is comprised solely of these heuristics. There are no items of astronomical knowledge or beliefs that BACON.1 draws on — the sort that Kepler *actually* drew upon as documented in the historical account of Kepler’s discovery of the third law *circa* 1619. The ‘discovery’ by BACON.1 was driven entirely by numerical data with no influence of the physical or astronomical aspects of the data, nor of any representation of the kind of physical intuition or meta-physics that drove Kepler in his quest for a quantitative law of planetary motion. It is difficult to believe that the contents of BACON.1’s discourse space had any resemblance to Kepler’s discourse space. There is also the crucial fact that the originating goal with which BACON.1 began its search for the law was not of its own making; it was *provided* as an input to the process.

So what can be said about BACON.1’s creativity? Clearly it was not H-creative with respect to the *human* history of science: BACON.1 did not in any way add to the body of knowledge about the physical universe. Nor, so far one can tell, was it consequential to the future history of either physics or astronomy; nor did it anticipate future discoveries — thus it was also neither C-creative nor A-creative. In the realm of understanding human creativity its one impact was to show that it is *possible* for an artificer to produce new rules or patterns by treating problems as exercises in formal symbol manipulation. In the context of the annals of *computational* creativity, on the other hand, a different picture obtains. It was certainly H-creative with respect to the history of computational

artifacts; and, insofar as it influenced future work in computational creativity, it was also C-creative. Therein lies its significance as indeed does the entire suite of programs Langley et al. built.

The complication that computational creativity poses (and human creativity does not), is that in the former, there are *two levels* of creativity: at the human level, the artificer is the computer scientist or programmer who builds a computational artifact (such as BACON.1) which performs certain kinds of tasks. Here, the human being is the artificer and the computer program is the artifact produced. At the computational level, the computer program or artifact is the artificer and the outcome of its particular task is yet another artifact (e.g., Kepler's third law or the proofs of logic theorems in the case of LT).

However, in *judging* creativity, there is no difference between the human and the computational levels: the only real option is the human consumer-as-judge. Judgement of BACON.1's creativity (or that of any of the other programs Langley et al. built) lies in the hands of human beings just as does judgement of Langley et al.'s creativity. So here lies the second major challenge for computational creativity: to design and build computational artifacts that can *themselves* serve as consumer-judges for the creativity of computational artifacts that are artificers.

There is yet a third challenge facing computational creativity research: Research into human creativity entails eliciting declarative knowledge ('know-that') about the nature of human artificers. Research into computational creativity also entails eliciting declarative knowledge about the nature of artifactual artificers; but there is the further step of inventing procedural knowledge ('know-how'): how to make such artifactual artificers.

Forging the Computational Creativity Discourse Space

Thinkers of many stripes have pondered the nature of human creativity for over two millennia. Thinking about computational creativity, in contrast, has a history that is barely seventy years old beginning with Alan Turing's celebrated 1950 essay "Computing Machinery and Intelligence". Thus, while the agenda of computational creativity has the undoubted advantage that it can build on what is known about human creativity, it has also branched off on its own to some extent, in part shaped by developments in AI but also in part stimulated by the specific conditions that underpin the *technological* aspects of the agenda. Computational creativity has thus forged a discourse space of its own.

Boden (2010) for instance has suggested that the act of production itself may involve three kinds of processes. The first entails making unfamiliar or unusual *combinations* of known ideas. This was actually proposed several decades ago by Arthur Koestler in the context of human creativity: he called it 'bisociation' (Dasgupta, 2019, pp 161–162). In the realm of computational creativity an example is the composer David Cope's (2005) system which selects particular elements of music from various compositions and links them together according to certain 'linking' rules of composition. In one situation Cope's program takes notes from different Bach chorales and linked them together to create its own original chorale which, in the words of Bruce Buchanan (2001) "Bach never wrote but might have" (p. 16).

Boden's second kind of process entails *exploring* a conceptual space. This, of course, is the now-classical idea of *heuristic search* — searching through a 'problem space' using heuristic rules to propagate and guide the search — pioneered by Newell and Simon (1972). A particularly notable system that combined both heuristic search and the combinatorial approach ('combinatorial search'), reaching back to the late 1960s and early 1970s was the DENDRAL system (Buchanan, 2001). Its domain was structural organic chemistry, and its task was to analyze mass spectrographic and other chemical data and infer plausible structures of unknown chemical compounds. DENDRAL was thus a computational artificer which produced as (abstract) artifacts, hypotheses about plausible chemical structures. Here, given a complete definition of the problem search space DENDRAL first generates all plausible combinations of elementary units (that is, combinations that satisfy specific chemical constraints, thus pruning away combinations that do not meet the constraints), then identifies all possible structural hypotheses that are compatible with the combinations previously generated. It then predicts consequences from each structural hypothesis, compares the predictions with the original spectrographic data, and finally chooses a hypothesis that best explains the data.

What was especially notable about DENDRAL concerned the judgement of the artifacts it produced. Its consumer-judges were professional chemists. In one 'experiment', an eminent mass spectroscopist asked graduate students and postdoctoral fellows attending his seminar on mass spectrometry to interpret three mass spectra from the empirical formulas of the compounds and these interpretations were compared with those of DENDRAL by mass spectroscopists. Their conclusions were that DENDRAL's performance was comparable to those of the graduate students and postdoctoral fellows.

Boden's third kind of creative process entailed *transforming* the rules or concepts governing heuristic or combinatorial search. For example, in contrast to DENDRAL's fixed set of heuristic rules, META-DENDRAL actually 'discovers' new rules. Here, given a set of data concerning known chemical structures META-DENDRAL infers rules that explain the data collection. Remarkably, some of the rules discovered by META-DENDRAL were sufficiently significant, chemically speaking, to appear in the chemical literature.

Clearly, the transformational process, operating as it does at the 'meta' level, is the kind valued most in the realm of human creativity (Buchanan, 2001). For instance, Thomas Kuhn's celebrated concept of paradigm shift, in the realm of scientific discovery, would constitute the highest form of transformational creativity (Dasgupta, 2019, pp 74–77, 79). And, indeed, this is how Geraint Wiggins (2006) who, offering a formal model of the computational creativity discourse space, interprets transformational creativity: he sees the transformational process as a meta-level search process. In contrast Buchanan (2001) cites the artist Harold Cohen's well-known AARON painting program which, despite its manifest creativity, will never choose to break the rules designed into it by Cohen.

When people generally ask what goes on in creativity, it is the process whereby an artifact is actually produced — the act of production — they really have in mind. Small wonder, then, that much of creativity research — in the realm of both human and computational creativity — has focussed on this core process.

For instance, most researchers seem to agree, whether dealing with human or computational creativity, that the act of production is *evolutionary* in nature. By this is meant that it is a gradualistic process. This is obviously the case for Boden's exploratory and combinatorial kinds of processing, but it is also evident in the transformational case. For, while a transformation (from one concept or rule to another, one paradigm to another) may *appear* abrupt or quantum change-like, closer examination reveals that at a finer level of detail, evolution or gradualism is at work. Picasso's mural *Guernica* (1937), an H-original artifact, would surely qualify as an instance of transformational creativity. However investigations into its act of production (Dasgupta, 2019, pp 153–161) reveal a distinctly evolutionary pathway.

This evolutionary notion is not a recent idea. In the language of AI, it is described most generally as the 'generate-and-test' heuristic promulgated most influentially by Newell and Simon (1972), although more recent computational creativity researchers seem to have re-invented the idea and given it their own names such as 'generate and explore' (Genenplore) (Finke et al., 1992) and 'engagement-reflection' (ER) (García et al. 2006). In the realm of science, there is a well known evolutionary model of the growth of scientific knowledge that closely adheres to the generate-and-test heuristic: given a problem to be solved the scientist proposes a tentative theory which is then tested against observations; if an error is found, the theory is modified to produce an improved tentative theory and so the process continues until a theory emerges that satisfactorily solves the original problem. Art historian E.H. Gombrich proposed a similar process in the realm of painting (which he dubbed 'making-and-matching') wherein the artist beginning with an initial schema (derived from past art) modifies it, matches the result against his expectations, finds a difference, modifies the artwork to narrow the difference, and so on (Dasgupta, 2019, p. 66).

The real disagreement between creativity researchers lies in the *nature* of this evolutionary process. One view, first advocated by Donald Campbell in 1960 and most vigorously promulgated by Dean Keith Simonton postulates a Darwinian type of evolution: in very general terms, given a goal, the creative process entails the blind generation of a compendium of artifacts in response, and the retention of that artifact that satisfies the goal. This model has come to be called the 'blind-variation, selective-retention' (BVSR) theory of the creative process. A wholly contrary view rejects BVSR theory as a *universal* model, especially the component of blind variation generation. This view argues that actual historical case studies of H-original and C-original artifacts reveal evolutionary pathways wherein gradual progress is made towards a satisfactory target artifact based on input from the artificer's world space, current goals, and the current state of the artifact-in-progress. The process is, rather, a case of *purposive evolution* since it is goal-directed (Dasgupta, 2019, pp 142–152).

It should be noted that the classical search strategies used in heuristics-based AI systems, — such as generate-and-test — are instances of purposive evolution. The Darwinian or BVSR strategy has been adopted under the rubric of *genetic algorithms* a computational strategy pioneered by John Holland in the mid-1970s.

As remarked, the process component of creativity has dominated the focus of both human and computational creativity researchers. But this by no means is to suggest that other aspects have been wholly ignored. Anna Jordanous (2016), for instance, has suggested that computational creativity should be investigated from the perspectives of the 'four P's': Person, Product, Process and Press. In the realm of human creativity this also is not a novel concept: In the language of this article, they refer to the artificer, artifact, act of production, and consumer-judge respectively. Jordanous makes the point that significant progress in computational creativity may obtain if all four P's are taken into account.

In the realm of the 'Person' (meaning the computational artifact-as-artificer) for instance, this may entail modeling personal human traits such as curiosity (Grace et al. 2017) or what Colton (2008) labeled the 'Creative Tripod' — skill, imagination and appreciation — as traits of the computational artificer. To these one might add superneeds (see section **The Judgement of Creativity**), such as the need to deviate from the norm, or other lesser but still compelling needs: the need to write, to paint, and so on.

In the case of 'Product' (the artifacts produced), the efficacy of computational creativity systems has been judged on the basis of the originality of the artifacts. This is hardly surprising given that the four types of creativity attributable to artificers discussed earlier (P-, H-, C- and A-) are defined in terms of the P-, H-, C-, and A-originality of the artifacts.

As for 'Press' (meaning the societal-cultural part of the artificer's discourse space) its significance lies in that just as consumers plays an essential role in judging human creativity, so also 'Press' will play a role in the judgement of computational creativity. At the very least this means that the design of a computational artificer should take into account the kind of consumers that will judge the system's creativity, 'Press' also has a role to play in considering 'Person': Colton (2008) has argued that a computational artificer need not necessarily possess such traits as curiosity, skill or imagination but should *appear* to possess such traits. Only then will the human consumer acquire at least the perception that the computational artificer is creative.

Most recently, using the 'four P's' as a framework, Lamb et al. (2018) have proposed a menu of heuristic rules ('takeaways' as they call them) as possible elements of the computational creativity discourse space which the designer of creative systems should take into account.

'Creativity but Not as We Know It'

Ultimately computational systems will be judged for their creativity according to the criteria set by human creativity studies. Anthropocentrism can hardly be avoided. But there is also the hope — and impetus — that computational artificers might be invented in

ways that are ‘non-human’ in some sense: that computational artifacts will exhibit creativity “but not as we know it” (Colton and Wiggins, 2016). Such artifacts will then manifest a variety of creativity that may be beyond normal human capacity – a situation wherein computational creativity may actually prove to be *superior* to human creativity.

How can this happen? One way is to extend combinatorial search into domains involving very large volumes of data — situations which humans are not very good at handling. The new science of ‘big data’ (data analytics) may be especially useful in such domains. For instance Varshney et al. (2013) describe a big data approach to the production of food recipes wherein not only is the volume of data large but is varied: large sets of existing recipes, data about food at the molecular-chemical level, and data about flavors. Their system deploys algorithms that generate thousands, even millions of new ideas from a ‘recipe space’, evaluates them according to criteria founded on both principles of neurogastronomy and psychophysics and selects the best ones. Thus, the act of consumption-judgement is itself integrated into the system as a component (called the ‘work product assessor’). Such judgment gives premium to both novelty and quality of the artifacts (recipes) produced. However, the resulting recipes have also been judged by professional chefs. The system is designed according to a model of the human creative process that is remarkably comprehensive in that it incorporates almost the full gamut of the ingredients researchers have come to identify in the realm of human creativity.

Computational Thinking, Redux

It seems appropriate to end this discussion where we began: in the realm of computational thinking. For, if “creativity, but not as we know it” is one way whereby computational creativity can go beyond the extent of human creativity, another is to draw on computational thinking to shed light on human creativity. The one represents a *concrete* (technological) embodiment of computational creativity; the other is a conceptual tool – an *abstraction* – to help understand human creativity.

In particular, the concept of the mind as a computational machine affords a powerful *metaphor* for understanding aspects of the human creative process. As an example, consider Gruber’s (1989) proposition that the creative artificer is usually engaged in a ‘network of powerful enterprises’ — that is, a collection of ‘related projects’ all of which contribute to the larger purpose at hand. The computational metaphor provides a basis by which one can more precisely characterize this idea by appealing to such computational processes as ‘parallel processing’, ‘time-sharing’, ‘interprocess communication’ and ‘multiprogramming’. Thus, Herbert Simon’s multidisciplinary creativity as an instance of Gruber’s network of enterprises can be explicated as a network of interacting, communications, time-shared cognitive processes, while the process by which Picasso arrived at his mural *Guernica* can be characterized in terms of the idea of multiprogramming (Dasgupta, 2019, pp 159, 184–192).

The computational metaphor, of course, serves as a *scaffolding*: once the metaphor has served its purpose it must be discarded. The verification or refutation of explanations is an empirical task that lies outside the metaphor itself.

Glossary

Close reading In literary studies, the careful interpretation or analysis of a text or passage of text, with focus on phenomena such as multiple meaning, paradox, or irony.

Digital humanities (DH) An academic application of computational tools and methods to traditional humanities disciplines such as literature, history, and philosophy.

Distant reading Data interpretive approach to literary collections, to seek and assess patterns in the history and evolution of literature and literary forms.

Formalism The study of art by analyzing or comparing form and style. Literary formalism is a type of criticism and theory, which concentrates on the forms and structures within texts as opposed to cultural contexts or external interpretations of texts. Well-known is Russian formalism, giving importance to the specificity and autonomy of the forms in literary language.

Psychometrics/psychometric Relating to the theories and techniques of psychological measurement.

Stylometry/stylometric The application of linguistic style to analyze written material. Often used to attribute authorship to disputed or anonymous documents.

Text mining The process of deriving information from text, also referred to as text analytics. The information typically emerges through the application of natural language processing and statistical pattern learning.

Introduction

Computer-assisted data analysis has become standard in many sciences, from traditional forms like physics and chemistry to new fields like bioinformatics (computational understanding of biological data). In the social sciences, computational data analysis is used to explore topics such as voting patterns, media coverage, and economic trends. In the humanities, where narrative data are paramount, computerized text analysis evolved to understand functional aspects of history, anthropology, philosophy, art, and

Table 1 General characteristics of traditional and computational approaches

<i>Traditional</i>	<i>Computational</i>

Meaning interpretation	Pattern recognition
What readers infer	How texts behave/function
What writers intended	How writers constructed

literary objects such as plays, short stories, and novels. Although CTA can be applied to any textual environment, this entry will address its employment in the evaluation of creative writing.

Though finer distinctions can be made between the terms *computerized* and *computational*, they are used in this entry synonymously. CTA includes an assortment of quantitative strategies such as text mining, analytics, and visualization. These strategies are central to disciplines such as computational linguistics and natural language processing, both of which are routinely applied to endeavors ranging from government intelligence gathering to consumer shopping habits. Topics in the humanities have also come under the scope of quantitative assessment, with computer-assisted approaches sometimes referred to as digital humanities (DH).

Neither CTA nor DH intend to replace traditional research methods but instead augment them. Computational researchers tend to be versed in the same historical and linguistic topics as other researchers, yet the power of the computer has opened additional avenues and led to new questions. A few key distinctions and terms between traditional and computational approaches to creative writing are shown in [Table 1](#).

Author Attribution

Identifying the author of a text and inferring characteristics about that author is a practice common in forensic linguistics, or the application of linguistic knowledge and methods to the context of legal disputes and criminal investigations. A particularly successful method for creative writing is *stylometry*, or the study of linguistic style. Stylometry started prior to the computer revolution but with mixed results. Humans write and read for content, organizing words into phrases and sentences to produce meaning. However, stylometry's success relies on detecting the frequency and placement of functional words like prepositions and pronouns, which carry an author's stylistic signature. As [Pennebaker \(2011\)](#) discussed in *The Secret Life of Pronouns*, analysis of functional language also reveals psychological characteristics (another type of style) about the text. In the case of a fictional work like a novel, functional language reveals psychological tone in the story, narrator, and what literary studies sometimes refer to as the implied author. Whether stylometric or psychological in scope, such detection often requires a level of quantitative data analysis too intensive for human readers working with paper and pencil. Not surprisingly, stylometry and author attribution studies advanced exponentially with the aid of CTA. The following two examples, of *The Federalist Papers* and the works of William Shakespeare, are well-known historical cases.

The Federalist Papers

Alexander Hamilton or James Madison, or both? In the history of attributing authorship, one of the most famous cases concerns *The Federalist Papers* (1787), a set of 85 essays and articles that influenced the ratification of the US Constitution. As known at the time, the authors of the entire collection were Alexander Hamilton, James Madison, and John Jay. However, 12 of the essays made particularly challenging arguments that no one man wanted to take responsibility for writing until years later, when Hamilton and Madison each claimed sole authorship. The issue went unresolved, as Jay died in 1802, and Hamilton was killed in a pistol duel with Aaron Burr in 1804, leaving Madison with no one to corroborate his own claim to authorship. Hamilton and Madison were of similar age and education, who had collaborated on several of the other essays in the collection, so determining who had written the 12 disputed pieces proved impossible through content analysis alone. The mystery continued to perplex American historians for nearly two centuries.

A breakthrough came in 1964, when statisticians Mosteller and Wallace applied Bayesian inference to functional word frequencies. Their conclusion was that Madison wrote the disputed essays. Although some historians remained skeptical, subsequent studies using CTA, in 1998 and again in 2003, supported the conclusion that Madison was the sole or at least primary author. In 2004, a CTA of representational language running throughout *The Federalist Papers* made a stronger case for Hamilton's contributions to Madison's writing.

Did Shakespeare Write Shakespeare?

No literary debate is more famous and polarizing than whether the plays of William Shakespeare were written by William Shakespeare, with conspiracy theorists alleging that the name Shakespeare itself was perhaps a pen name for an anonymous author. The

controversy began in Victorian Britain and led to a feud in academia over textual discrepancies in the Shakespearian canon, a controversy clouded by the factual and mythical narratives regarding the real life of Shakespeare. Researchers began using traditional text analysis early in the 20th century to help deal with the discrepancies, which addressed a few questions but left many unanswered.

In research published in *The New Oxford Shakespeare: Authorship Companion* (Taylor and Egan, 2017), the latest in stylometry and CTA was employed on the 44 plays of Shakespeare (the known canon of 37 plays plus seven suspect or misattributed titles). For decades, the Oxfordian view challenged the traditional, Stratfordian perspective that Shakespeare was the lone and original author of all works bearing his name. This time, the research confirmed arguments from both camps. On the one hand, Shakespeare appears to have written all 44 plays to his credit. On the other hand, as many as 17 of those were collaborations with other writers, including long-time suspect Christopher Marlowe. In independent research that supported the conclusions, Boyd and Pennebaker (2015) mapped the psychological signature in *Double Falsehood*, a play believed to have been written by Shakespeare but commonly attributed to an 18th century author. The CTA of all potential writers clearly indicated that this title was Shakespeare's but also a collaboration with known colleague John Fletcher.

Features of CTA

Levels of Inquiry

Advantages of CTA include the levels at which such analyses can focus. Whereas traditional close reading and analysis tend to operate at one level of data, where the human reader is what Franco Moretti (2017) called "an anthropocentric scale" (p. 65), CTA can approach the data at multiple levels.

Microanalysis

CTA can identify patterns and features within texts that escape human readers. Microanalysis is the closest extension to the traditional method of close reading. However, written narrative has evolved throughout the centuries, and spoken forms of narrative are prehistoric, leaving human readers culturally and psychologically conditioned to read texts in particular ways. Computers can evaluate operationalized variables and be programmed to find patterns on their own, to show, for instance, how particular novels or novelists use certain types of language or topics and how those types unfold over the duration of a narrative. An example is the novel *Moby Dick* (1851), in which Jockers (2014) quantitatively illustrated how references to Captain Ahab negatively associated with references to the Whale. The pattern showed how author Herman Melville used his narrator, Ishmael, to frame Ahab and the Whale separately, setting them up as two titans headed toward classic confrontation.

Macroanalysis

CTA can read text collections too large for human readers. Macroanalysis evolved as computing power expanded and print objects such as novels increasingly became digitized. Compared to the traditional method of choosing certain texts and drawing conclusions about literary canons, genres, or histories, computers can process hundreds of variables and thousands of volumes in a targeted genre, corpus, or archive. Working at this level is productive when tracking macro evolutionary changes in literature. Fig. 1 shows a word-frequency macroanalysis of gender references in a corpus of American fiction writing over 16 decades (1850s–2000s). The vertical axis illustrates the ratio between the frequency of words operationalized as *female* (e.g., she, her, sister) and *male* (e.g., he, him, brother). The comparatively low frequency in the appearance of female references (i.e., female characters and agency) occurred through the decades of the 1910s through 1980s, with a female peak in the 1870s and again in the 1990s through 2000s (see Novels on history regarding gender).

Figure 1 Word-frequency ratio of *female:male* references (variables) in American fiction, decades of 1850s through 2000s. Each variable operationalized in the 2015 edition of *Linguistic Inquiry and Word Count* (LIWC2015), the software used in the study. The data are from the Corpus of Historical American English (COHA) (<https://www.english-corpora.org/coha>). From Fairchild, T. E. (2019). *Emotion, Embodiment, and the Novel: Word-Frequency Characteristics and Dystopian Masterworks*.

Mesoanalysis

CTA can help identify and track links between micro and macro levels of data. In response to the stricter parameters of micro and macro analyses, mesoanalysis has become the preferred approach in DH and CTA research focused on meaning and connection in creative writing. The mesoscale was an idea adapted from meteorology, a level of data interpretation that links local weather events to larger scale atmospheric activity. In a digital literary study, a mesoanalysis might connect patterns running through individual texts or authors to broader patterns in corpora or language. In a doctoral dissertation in classical studies, [Marley \(2018\)](#) analyzed the writings of eminent Roman orator Marcus Cicero (106–43 BCE). Although Cicero is a well-studied historical figure, Marley's CTA revealed new insights about his writing and life. Marley processed Cicero's letters through the open-source software tools RStudio and Gephi to build a visual network of his peers and interactions. The researcher also employed sentiment analysis (natural language processing of subjective information) to track the affect trajectories of Cicero's speeches and contextualize them against Latin rhetorical theory and modern social-psychological theories on ancient emotions.

Techniques

Three key concepts in computational criticism are frequency, shape, and space, which build off one another.

Word Frequency

Word counting contends with frequency in data and is an early and comparatively straightforward strategy, a process that originally used manual counts (with paper and pencil) to build operationalized word sets for statistical analyses. The labor-intensive slowness of this method meant a limited number of variables and a limited number of texts, a problem overcome since by the expansion of computing power. Word-frequency analysis remains the easiest method to understand and implement, and is supported by a variety of software applications, ranging from free-download tools to professional packages (refer to [Fig. 1](#), for visual example of word-frequency research).

Topic Modeling

Model building addresses shape and space in data and has a long and successful track record in the sciences. The specific technique of topic modeling originated in computer-assisted linguistics, where software categorizes the words of a document into mathematically correlated clusters called *topics*. Like word-frequency method, an advantage of topic modeling is that it can be applied at any level of inquiry, from the individual poem, article, or book to literary corpora or newspaper and journal archives. Unlike word-frequency method, topic modeling is a type of text mining, the most advanced of which takes advantage of machine learning: algorithmic use of patterns and inferences to learn directly from target data rather than following explicit human instructions. Specific and useful mining processes include text clustering, concept extraction, and association analysis, as well as the network nodes, sentiment analysis, and visualization techniques used in [Marley's \(2018\)](#) study of Cicero. Text modeling has developed into a favorite approach for many researchers in the digital humanities, including the [Archer and Jockers \(2016\)](#) research on bestselling novels discussed later.

Narrative Space

Spatial tracking and awareness originated in the ancient field of geography, for constructing maps and navigating locations. In narrative studies, spatial tracking applies to the representation of physical places in texts but also to the topical and thematic allocations of narrative space, a space that is itself organized around time. Examples include two experimental historiographies by CTA pioneer Franco [Moretti \(2005\)](#), who mapped the 19th century European novel onto physical histories of Europe, and then used maps, charts, and timelines to visualize a larger system of world literatures. Another example involves a Euclidean distance metric (a vector measurement between two data points), combined with a phylogenetic tree (a visual used in evolutionary biology), which together map spatial distances between individual sets of texts. [Fig. 2](#) illustrates this example, of five language types from the Corpus of Contemporary American English (COCA) processed through 10 psycholinguistic variables (see [Table 2](#)). The research result indicated that fiction writing was the most distinct among the types.

Figure 2 Euclidean distances for 10 psycholinguistic processes. The unrooted tree shows fiction as the most distinct of five types.

Table 2 Euclidean distances for five language types

COCA: Euclidean distance (d)				
	Magazine	Newspaper	Academic	Fiction
Spoken	3.48	3.97	4.08	6.26
Magazine	-	1.56	2.72	4.89
Newspaper		-	3.09	5.23
Academic			-	6.66

Euclidean distances for 10 psycholinguistic processes (from LIWC2015) applied to COCA (<https://www.english-corpora.org/coca>). The numbers are relative scores of how distinct the language types (fiction writing, magazines, newspapers, academic, and spoken language) were from one another (the larger the number, the more distinct). From Fairchild, T. E. (2019). *Emotion, Embodiment, and the Novel: Word-Frequency Characteristics and Dystopian Masterworks*.

Software

Numerous software options exist for doing CTA. These range from general computational and statistical programs to specific frequency, modeling, and visualization applications, both free and licensed. The type of CTA lends to the platforms and packages used, with individual fields and academic programs each having their respective histories and preferences. The following is a short list of desktop software with track records in research on creative writing:

- *RStudio*. An open-source (free) software interface for the R statistical computing environment. R is a vector language requiring computer programming skills, which RStudio turns into a GUI (graphical user interface) with drop-down menus more easily accessible to the less technical user. Much of the power of R resides in the hundreds of free support packages developed by global R developers: collections of functions and compiled code designed for tasks such as analyzing evolutionary patterns and drawing graphical illustrations. R computing has become a popular platform in literary studies, programmable at the micro, macro, and meso levels.
- *Linguistic Inquiry and Word Count*. A word-counting engine but with a psychometrically validated word dictionary that makes the software into a tool for psychologically evaluating individual texts and entire corpora. LIWC (pronounced “Luke”) is a commercial program in its fourth edition as of year 2015. It has been used in published research on a variety of writing types: (i) student essays; (ii) the expressive journals of clients undergoing therapy; (iii) poetry and prose fiction (see [Boyd and Pennebaker, 2015](#), on Shakespeare study); (iv) newspapers and other periodicals; (v) webpages; (vi) blogs and Twitter accounts; and (vii) affective responses in the aftermath of the 2001 September 11 attacks, research which led to the formation of a new emotional tone category in the LIWC2015 edition.
- Other software available for standard computers include: *Gephi*—open-source network analysis and visualization; and *Rapid-Miner Studio*—commercial package for overall data mining and analytics, applicable to text.

Procedures

Whether on fiction or nonfiction, conducting CTA typically begins how any scientific study begins, by formulating a research question. The researcher must also determine the data source, usually an available corpus or a set built specifically for the research. If the latter, the researcher must find, acquire, and prepare the data just as any analyst would. If conducting CTA on the canon of Shakespeare, for instance, the researcher would need electronic (digital) copies of the works in the canon, which are currently in the public domain. If conducting CTA on someone like a living novelist, who is not in the public domain, the researcher would need to acquire digital versions of the novels legally. In the case of tracking writing such as individual blogs, or the evolution of language in the World Bank’s Annual Reports since 1945 (see [Moretti, 2017](#)), or the tone of the entire *New York Times* archive, each would require a particular approach to data acquisition. Once the textual materials have been acquired, they must be cleaned of extraneous information such as editor’s notes, leaving only the targeted content for analysis. These acquisition and preparation steps can be performed individually by the researcher, but with large datasets a software platform like R can be programmed to assist or conduct them automatically (see [Jockers, 2014](#)).

Digital texts, archives, and corpora exist in a variety of sources. Two that are readily available on the Internet and have been used in peer-reviewed research include:

- *English Corpora* (www.English-corpora.org). The site offers publicly accessible English corpora, with individual corpora organized around writing types such as American contemporary, American historical, early British, web-based, and Internet news.
- *Project Gutenberg* (www.Gutenberg.org). This archive offers nearly 60,000 free eBooks, which include every major literary work in the public domain. The archive is a popular mining source for historical literary research appearing in peer-reviewed studies. Because the texts are in the public domain, and domain laws vary by country, the archive includes only a small collection of titles published in the 20th century, which limits research to mostly the 19th century and earlier.

In Practice

Writing a Novel

Perhaps the single biggest concern in moving the humanities into computational, data-driven, quantitative territory is based in the fear of defacing or corrupting accepted beliefs about writing and writers, both individually and collectively. In a quantitative data approach on novels and how to write them, Blatt (2017) examined more than 1500 texts, which included classic and contemporary bestselling novels, bestselling writers' guides for aspiring novelists, and amateur and self-published works of fiction. From the evidence, Blatt came to two important conclusions:

1. advice on how to write a successful novel is inconsistent among experts; and
2. amateurs like fan-fiction writers have yet to graduate to successful novelists.

Blatt's first conclusion represents a criticism of the lucrative how-to book market on writing fiction and becoming successful. Though the essential aspects of storytelling and narrative form are rooted in human psychology and have changed little over the centuries, specific language and its implementation face continuous evolutionary pressures, from markets, readers, critics, writers, and culture at large. The upside of Blatt's conclusion was that, given the inconsistencies regarding the path of a writer's success, aspiring novelists can take comfort in knowing that a one-size-fits-all recipe does not exist.

Blatt's second conclusion represents a cold reality for the same aspiring novelists. While computers have made it easier for individuals to sit at a keyboard and produce language, sometimes churning out millions of words of fiction per year, Blatt's research showed that the practice alone simply does not lead to publishable authors. Despite the lack of consistency in what constitutes good novel writing, a consensus does exist on what constitutes poor writing, which corresponds strongly to not being published. From a creativity perspective, fiction writing is a domain-specific craft, requiring a great deal of time and practice to master. To become a successful novelist, a writer must develop a discipline for crafting and editing, and for shopping a manuscript that can be sold as a product.

The Blockbuster Novel

Catchy titles that imply definitive answers on the production of art tend to be treated skeptically by experienced artists and critics alike. In *The Bestseller Code* (2016), however, the researchers were veteran literary agent Jodie Archer and literary text-mining pioneer Matthew Jockers, each associated with major computational text labs that support studies in language, history, and anthropology. Their primary research question asked: What do novels from the *New York Times* bestseller list have in common at the level of textual characteristics? The task appeared daunting since almost any genre, theme, and style of writing has historically become a bestseller at some point, from Pulitzer Prize winners, to romance novels, to the likes of *The Girl with the Dragon Tattoo* (2005), a tale published posthumously by a Swedish political writer that contains explicit scenes of sexual violence.

The fiction retail industry is organized around the assumption that the most important aspect for the reader of a novel is what the novel is about. Accordingly, the issue of bestselling title has invariably been left to publishers and market researchers, most of whom treat such works as luck of the draw. The result is that the current trend in fiction publishing is for companies to allocate most of their budgets to an underdiversified portfolio of high-profile veteran authors, which ensures some intermediate profitability but represents a poor investment strategy in the long term, to the industry economically and to the culture in general. In analyzing nearly 5000 novels through a text mining strategy, Archer and Jockers hoped to construct a method by which to identify potential bestsellers among new and unknown authors, which could be used to help develop writers, writer programs, and ultimately a better-functioning fiction industry. Although one writer might produce thrillers and another romances, if both are highly successful, then both must be doing something in the same way.

Using traditional text analysis to examine what this same way might be would have required years of close reading my multiple readers, but a pair of individuals working computationally needed only a few months. Most of that time was spent programming the algorithms necessary to clean, convert, read, and analyze the text data. The computer must be trained to read every word within the context of surrounding words, which Archer and Jockers (2016) did by topic modeling through R programming. Although the researchers did not, nor intend to, provide definitive conclusions about the construction of bestselling novels, their machine algorithms correctly identified nearly 85% of the bestsellers from a set containing thousands of titles. When compared to non-bestselling novels, some recurring and telling patterns that emerged regardless of genre, style, or author popularity included:

1. *Common and grounded topics*: despite the prevalence of titillation and the fantastic in popular culture, these patterns appear far less frequently in bestsellers than in non-bestsellers. For instance, Danielle Steel romance novels are among the bestselling titles in history, in which the three most common topics do not include passion or explicit romance, but are *home*, *family*, and *medical*, with the specific topics of *sex* and *drugs* making almost no appearance.
2. *Focused topics*: bestsellers offer fewer topics, ideas, and subplots, and generally 30% of the narrative space focuses on the central topic or idea. For instance, John Grisham is known for legal thrillers, and approximately one-third of a given Grisham novel focuses on the model topic of *legal*, meaning the scenes or conversations entail some aspect of the law or legal system.

3. *Human closeness and connection*: intimacy over sex; a meal with a friend rather than a night on the town; locations that are familiar rather than exotic; dilemmas that are emotional or ethical rather than political or ideological. In short, for readers of popular fiction, bestselling novels address the ordinary aspects of real lives in familiar settings.

So how does any of that account for the blockbuster success (over 40 million copies worldwide) of a title like *The Girl with the Dragon Tattoo* (GDT), one rife with deception, corruption, revenge, and depictions of sexual violence: a dark if not unnerving novel that was dismissed by most American publishers and critics as offensive to literary values and American sensibilities?

The same machine learning algorithms that correctly identified over four-fifths of the bestsellers from a sample collection also gave GDT a bestseller probability score of 93%, based mostly on the category of female agency. The novel's female protagonist, Lisbeth, is a moody, self-focused computer hacker declared psychologically unstable by the state and motivated by retaliation: a young tattooed woman that exudes the opposite of traditional feminine qualities typically seen in bestsellers and most other narratives featuring female leads. However, the Archer and Jockers machine program also recognized Lisbeth as intelligent, resourceful, confident when necessary, and an underdog who is ethically superior in terms of her conviction to exposing violence against women: all the components that make for a powerful antiheroine. Despite the explicit scenes and Sweden-specific political intrigues, GDT also scored high in the essential bestseller territory of human closeness and connection. For all her external appearances and behaviors, Lisbeth is alone, longing for true companionship, falling in love with the novel's principal protagonist, an older man who can never reciprocate her feelings.

Evolving Language of the Novel

The final examples of CTA application are some of the most academic, most experimental, and most creative. Published by the Stanford Literary Lab under the title *Canon/Archive: Studies in Quantitative Formalism* (Moretti, 2017), much of the research addressed the evolution of novelistic language, research that tests institutional and popular boundaries regarding the interpretation of fiction writing.

In one of the studies, the approach borrowed musical principals such as crescendo to explore the narrative sense of loudness in 19th and 20th century novels. Musical compositions are played in notes and arrangements but also at changing volumes, both auditorily and perceptively. In a microanalysis of dialogic loudness, the research considered Part I of Dostoevsky's *The Idiot* (1869), which provided a working model for the relationship between word choices, characterization, and how loud the text (narrator) feels to the reader. The researcher operationalized exclamatory, punctuated, and critical language (e.g., *My God!*; *Don't blather*; and *What?*) as dialogically loud. As the data indicated, loudness applied in varying degrees to each character except one: Prince Myshkin, the protagonist. Dostoevsky wrote Myshkin as an embodied representation of honesty and integrity, which earns the troubled prince the reputation of idiot. As the language data showed, Dostoevsky used neutral expressive language only when writing Myshkin's character and dialog, segregating the prince from the chorus surrounding him, a chorus that collectively represents deceit, corruption, and moral emptiness.

Another study from the Stanford series examined the paragraph in the novel, a comparatively under-investigated construction. One conclusion was that different scales of study bring forth different features. Previous research showed how word tokens (i.e., research at the level of the word) are effective at distinguishing literary genres and one author from another. Likewise, sentences have proved useful in distinguishing writing styles. The paragraph, by comparison, is a construction that helps carry forth novelistic theme and motif.

In a third study from the Stanford collection, the research switched to the geospatial mapping of fictional London in 18th and 19th century British novels. Despite the radical growth and changes to the real city during the 19th century, the fictional city changed little, with authors revisiting well-known locations again and again, particularly the West End. The research also attempted to map emotional identifications in these novels with specific London locations. In agreement with additional research on loudness, the main conclusion was that British novels, including those set in London, underwent a quieting of exterior emotional expression, which matches qualitative research on the evolution of British fiction.

Implications

An implications section is included because new innovations almost invariably challenge established convictions. To date, CTA researchers working on creative writing must not only continue developing CTA methods but do so in a climate that often misunderstands or misrepresents their efforts (see Blatt, 2017, and Moretti, 2017, on the polarized nature of reactions to CTA in literary studies). Technology is a human-driven enterprise that changes humanity's relationship with knowledge, with creativity, and with itself. An example with far-reaching implications concerns the mechanical moveable-type printing press, which revolutionized the book and paved the way for mass literacy yet also caused radical change to the existing institutions and ideologies of the day. For Christianity and Western culture in general, the mechanical press produced the Gutenberg Bible, which inspired a print revolution that helped shift the power over belief from the church and educated scribes to anyone who could read. One major result was the European (Protestant) Reformation, which began with printed pamphlets and led to a religion more focused on scripture, the New Testament (NT), which in turn required a more literate population—the spread of the Koran played a similar role in the Arabic world.

Skipping to the present, computers are the latest phase in the evolution of print technology, where the long-term implications are equally as radical. Biblical scholars already arrived at a consensus that characters like Moses are fictional only, not historical. Through a combination of research in history, anthropology, and textual linguistics, scholars additionally concluded that the Christian NT contains numerous inconsistencies, revisions, and even forgeries regarding the story of Jesus. The conclusion was that the NT should be treated as a work of literature, not a historical document, thus separating the Jesus of the Bible from whomever the historical Jesus might have been. Rather than resolving a dilemma, this separation invited more questions. Applying Bayesian conditional probability to indepth textual analysis and the known historical record of the ancient Near East and Roman Empire, [Carrier \(2012\)](#) concluded that a historical Jesus, like Moses, never existed, leaving only the mythical character to consider.

Although computerized text analysis in most creativity-related research is less consequential than rethinking the core of a religion, the way that language, particularly written language, is researched and evaluated has already begun an evolutionary shift. The long-term implications can only be glimpsed, but centuries of advances in human science and understanding are becoming more necessarily interwoven with advances in computing power. This relationship should not be considered as the past being replaced by the future, but as forces evolving together to create an expanded paradigm. The book itself, for instance, is a technological achievement, but hand-copying volume after volume was ultimately inefficient, leading to machinery that advanced printed material to the forefront of modern civilization. Likewise, intuitive paper-and-pencil observation and analysis is the foundation on which modern scientific research methods are built, but delving deeper into mysteries such as the genome, or tracking exactly how many feminine pronouns occurred in the evolution of 19th and 20th century novels, requires machinery that can accurately process quantified datasets. Though genome research has the potential to resolve the much greater problem of cancer, understanding the trend of feminine pronouns is important for constructing an accurate history of female authors and characters, and thus challenging portrayals of women based on cultural ideology and rhetoric. At smaller scale, understanding the linguistic mechanisms employed by someone like Dostoevsky informs fiction writers and critics of the metaphorical brushstrokes by which such artists paint.

Feedback for Creative Writing

Approaches utilizing computerized text analysis offer new and interesting ways of assessing and ultimately understanding all manner of writing including creative writing. These approaches also present new methodological, empirical, and institutional challenges. As an outcropping of linguistic formalism, CTA is part of a movement to assess language by its moving components, arrangements, and designs. The formalist position began in response to the long history of hermeneutic assessment, a practice focused on content and meaning, which still informs linguistics and verbal art studies. However, formalists argued that content analysis alone presented two fundamental problems: (i) too much subjective interpretation on the part of the reader, and (ii) little consideration of linguistic architecture, which is problematic since language itself is a rule-based architecture.

From a creativity perspective, an additional argument is that readers encounter texts far differently than writers produce them. Fundamentally, reading is an act of interpreting, whereas writing is an act of constructing. Construction requires an understanding of structure. Yet nearly all feedback for established and developing writers comes in the form of reader criticism, feedback which often says more about the reader's psychology than the creative writer's needs (see [Maass, 2016](#), on reading as a process guided by emotional preferences). Feedback by expert writers and teachers is generally more helpful to the creative writer, but as [Blatt \(2017\)](#) demonstrated in the case of the novel, there is no reliable consensus as to what constitutes good writing. By comparison, CTA is a form of data science, which means the results are repeatable and thus tangible to the creative writer. A CTA can provide such information as verb counts (activity), how much narrative space a text is giving to which narrative topics, and the psychological characteristics of the protagonist, the narrator, or the entire text. Such detail might be of limited interest to a reader, but to a writer they are the equivalent of a songwriter's relationship to notes, chordal progressions, and arrangements. If applied accordingly, CTA has the potential to become a developmental tool in creative writing.

Introduction

Chat Conversations

In recent years, almost everybody uses online communication and collaboration tools available through the Internet and Web, on a large diversity of devices including laptops, desktops, smart phones, and tablets. Among other tools, textual communication and multi-participants conversations using instant messenger (“chat”) became a practice that takes a lot of daily time. In addition to the advances in providing such communication tools, computer technology is now, on a permanent higher degree, including recent improvements in Artificial Intelligence (AI) technology. Though, even if AI applications perform nowadays remarkably in many tasks, and expectations are great that this technology will replace humans even in some intellectual activities, creativity is still a feature in which humans cannot be outperformed by computer programs. However, AI provides the means for empowering humans in their creative activities: AI-based Natural Language Processing (NLP) of the recorded conversations (the “chat logs” in textual format) can extract various data, such as creative ideas emerged during the conversation, features of participants relevant to the decisions on the composition of teams performing tasks involving creativity, and even hints for utterances to be emitted by an AI conversational agent that might foster creativity.

While many online conversations have only communication or socialization purposes, there are also two important domains where chat conversations can bring an important contribution: creativity fostering and creativity detection in Computer Supported Collaborative Learning (CSCL). The usage of conversations to foster creativity is often used in companies or in other work-related or educational settings in the form of brainstorming and its many variants. Usually these conversations are face-to-face but having them at a distance in the form of video-conferences or chat sessions is not a problem. Face-to-face discussions or video-conferences may be transcribed for further analysis, which in fact makes them closer, from the computer processing point of view, to chat logs. However, chat applications have a specific quality: they support the development of multiple discussion threads in parallel, especially if they have the facility to explicitly reference previous utterances in the dialogue (Mühlpfordt and Wessner, 2005). In speech-based conversations this is not the case, as only one speaker can take the floor and this feature makes it very difficult having more than one discussion thread at a given moment.

Creativity in CSCL Chats

CSCL is characterized by knowledge construction in small groups of students, face-to-face or chat conversations being one of the simplest and most efficient communication methods to support collaborative knowledge construction (Stahl, 2009). Creativity in CSCL chats should be supported in two ways: by designing assignments that foster creativity and by developing software tools able to identify creativity in the resulted chats, which allows analysis, feedback, and grading.

The development of software for analyzing CSCL chat sessions is very important in the context of the spread of Multiple Open Online Courses (MOOCs), in which several thousands of students follow online or recorded video lectures. In this context, automatic grading of assignments is mandatory as it is impossible to have enough human teaching assistants for manually assessing students’ homework. One possibility is to give students assignments to be solved collaboratively in chat sessions, but this solution should be supported by automatic analysis software tools, as described in this chapter.

Knowledge construction in CSCL chat sessions involves creative processes in at least two ways: discovering how to solve a given problem – for example, in mathematics (Stahl, 2009), and uncovering new features and relations regarding the concepts presented in the lectures. Chiu (2008) used the term “micro-creativity” to denote “an expressed idea that is new relative to the group members’ experiences” – that means a creative act performed in groups of students during CSCL sessions. In fact, one important dimension in education is to foster creative thinking skills in students. One way of achieving this goal is to design assignments that engage them in polemical discussions like, for example, debating about the concepts presented at lectures (Trausan-Matu et al., 2014). Moreover, chat environments should be enhanced with facilities for inducing inter-animation (Trausan-Matu, 2010) and flow state, the latter becoming in conversations a group flow state: “the most common place people experienced flow was in conversation with others. At work, conversation with colleagues is one of the most flow-inducing activities (...) Conversation leads to flow, and flow leads to creativity” (Sawyer, 2015). In this sense, chat systems having explicit referencing facilities enhance message production (Mühlpfordt and Wessner, 2005) and polyphonic inter-animation (Trausan-Matu et al., 2007), which may be compared with jazz improvisation, which generates group flow and group creativity (Sawyer, 2015).

The idea of engaging students in polemical discussions on concepts from the learning domain encourages them to take divergent positions. However, in order to obtain a constructive result, the discussions should be conducted towards eventually finding convergences that solve the introduced divergences. Such an approach has been used for a series of CSCL chat sessions that were given as a homework for undergraduate students in their senior year at the Human-Computer Interaction course at University Politehnica of Bucharest. The students had to discuss for 1–2 hours in groups of 4–8 participants, on a chat platform with explicit referencing facilities. Each of them had to choose a collaborative web technology (e.g., online forums, blogs, chats, wikis, and Google Wave) and were instructed to take the role of a company manager who should promote in the conversation their technology and, meanwhile, criticize the others’ technologies. They were told also that in the end they should work to find a solution to integrate the different technologies taking into account their different advantages in the idea to have a convergent step in the final part of the conversation that should integrate the ideas developed in the divergent phase (Trausan-Matu et al., 2014).

The assignment described above is, in fact, following the recommended divergent-convergent 2-steps schema for fostering creativity. One key factor that influences creativity is the presence of divergent ideas. As Mann and Cadman (2014) wrote, “There are no set answers to creative problems, but divergent thinkers can come up with a range of novel answers”.

Creativity from a Linguistic Perspective

One definition of creativity, which follows the above-mentioned divergence-convergence steps, is “the ability to see a challenge or a problem in a new light and to find solutions, which were not obvious” (Weston, 2008). Veale saw creativity from a linguistic perspective as “new and creative ways of expressing a given idea” (Veale, 2011), therefore, a different way of writing (and, implicitly, thinking) about given concepts. In this sense, creativity is directly related to the usage of metaphors and analogies. In addition to metaphors, other linguistic phenomena related to creativity were investigated, such as irony, humor, and similes.

Metaphors are used in a very important amount in our lives (See Metaphors). However, in CSCL chats it is hardly expected that students would use novel metaphors. A rather easier task related to identifying creativity in chats is the identification of potential new ideas, starting from the identification of the concepts in text and considering their semantic closeness to the domain of discussion. Such an approach is the subject of another section of this chapter.

Jokes and, more generally speaking, carnivalesque (Bakhtin, 1984; Trausan-Matu, 2010) also may be divergent steps, which can drive towards solving a problem. Such an example can be found in a chat of a group of students that collaboratively solve a mathematical problem (that was not solved individually by neither of them). An intervention of one of them that masquerades as mathematical reasoning (followed by utterances of “haha” by him and the others) was the spark that drove the group to find the solution of the problem (Trausan-Matu et al., 2007).

The identification of potential creative elements in texts may be done also starting from the formation of new words and, as some sociolinguistic studies showed, usage of a language which is perceived as “unplanned and unrehearsed, constructed on the hoof, whether it represents a brief, even fleeting (re)framing in which the interaction is temporarily keyed as artful/creative, or forms part of a more sustained creative interchange” (Maybin and Swann, 2007).

For both fostering creativity and CSCL knowledge building tasks using chats, statistical analysis tools and NLP technologies are very helpful for the identification of new ideas and, especially for understanding the creative characteristics of participants. An example of analyzing several creativity features with statistical methods for face-to-face conversations involved groups of four students engaged in solving a mathematics problem using a “code and count” approach proposed by Chiu (2008). Such an approach has two steps. First, utterances are manually annotated with codes, for example, speech or discourse acts. For example, in Chiu’s approach five dimensions of coding are used: (1) evaluation of the previous action (agreement, disagreement, ignore, introduction of a new topic), (2) knowledge content (new idea, repetition, or off-topic content), (3) validity, (4) justification, and (5) form of invitation to participate – which are a kind of speech acts. In the second step, statistics are computed (for example, how many new ideas were introduced) and, even complex data is extracted, as micro-creativity (for example, new ideas that are correct). The second step may be also the subject of machine learning in the idea of training a model, which may be used for automatically identifying micro-creativity in chats.

A Dialogistic Analysis of Creativity in Chats

The strong connection of conversations (and dialog, in general) with creativity was also emphasized by Mikhail Bakhtin: “Dialogically seen, information is not transferred, but, rather, produced. (...) dialogism could be seen as a type of creativity” (Lähteenmäki and Dufva, 1998). He introduced the idea that dialogism is a fundamental philosophical category and that dialog is omnipresent. A very important remark of Bakhtin is that truly creative words should contain more than one voice (voices, seen on a generalized sense, as ideas (Trausan-Matu et al., 2014)): “any literal, single-voiced word is naive and unsuitable for authentic creativity. Any truly creative voice can only be the second voice in the discourse” (Bakhtin, 1986). In addition to this multivocality, Bakhtin emphasizes the polyphonic weaving of voices, in an analogy with the musical case, where several voices co-occur keeping their own “personality” but achieving a coherent whole. Voices generate dissonances (divergences) which eventually are “solved” with consonances (convergences), thus the polyphonic phenomenon being a place for creativity.

The detection of “second voices” and polyphony is hard to grasp automatically with classical NLP tools. However, a semi-automatic approach may be implemented, and several applications have been developed starting from this idea, such as PolyCAFe or ReaderBench (Trausan-Matu et al., 2014). Moreover, patterns of divergence and convergence (Trausan-Matu et al., 2007) may be identified as indicators of a polyphonic weaving.

PolyCAFe was developed for analyzing the individual and group contributions of students engaged in chat conversations in CSCS assignments of the type discussed above in this chapter. It uses NLP techniques for detecting the concepts from a chat. These are presented to the user (see Fig. 1), thus supporting her/him to identify new concepts (“second voices”), with creative potential. For example, in Fig. 1, the concept “post” may be identified as a “second voice”, which can drive to creative ideas by inter-animation with the “primary voices” (wiki, blog, forum and chat) – the concepts that were imposed as subjects of discussion.

PolyCAFe has also graphical visualization facilities, which may be used for analyzing how the “second voices” manifest along the chat (see Fig. 2). Moreover, the system, starting from the polyphonic weaving, computes a measure of inter-animation (Trausan-Matu et al., 2014), whose evolution in time reflects the variation of collaboration (see the graphical representation in the middle

Figure 1 Feedback provided by PolyCAFe about frequent concepts.

Figure 2 The evolution of the usage of the “post” concept, candidate for a “second voice”.

of Fig. 2). The zones with a high collaboration/inter-animation are zones in which group flow may have occurred and, consequently, their utterances might contain creative ideas.

Corpus-Based Creativity Identification in a Group of Related Chats

The method presented above is useful for analyzing a single chat conversation. However, if multiple such conversations that debate similar concepts are available (as is the case in the context of MOOCs), then another type of analysis can be performed. In this case, the content uttered in each conversation from the corpus may be analyzed with the purpose of identifying significant similarities and differences between them. The intuition behind this analysis is that the similar parts that are observed among the chats represent common, ordinary knowledge, that is known and accepted by most participants and thus cannot be considered creative. In the same time, the observed differences – elements that are not common and are presented only in a few chats – represent intended deviations from the commonly accepted concepts. These deviations may be treated as signs of creativity or divergent thinking, considering that linguistic creativity is linked to the unpredictable departure from regular rules. Practically, the main assumption of this method is that “creativity can be linked to differences in the participants’ discourses, rather than to creative manifestations in language, which are difficult to identify and assess” (Chiru and Rebedea, 2017).

Thus, a software application was developed with the main purpose of identifying the segments containing ideas that are not usually generated. This is achieved by comparing the current conversation with lots of other discussions on the same topic (the more such conversations are available, the more reliable and interesting results, related to creative talk, may be generated). To this purpose, the content of the current conversation is analyzed to detect new (creative) ideas and then to see what happened to them – if they were subsequently exploited (the conversation insisted on those ideas) or lost (used once and never repeated) (Chiru and Rebedea, 2017). This application is a first step in supporting creativity in chats by highlighting the novel concepts present in the corpus (*new ideas*) and considering them to be creative and also by identifying topics that could have become important, but they were forgotten during the debates (*lost ideas*).

However, not everything that deviates from the standard is creative, some of these deviations could be simply off-topic and should be treated as such. Therefore, a method that could discriminate between the two possible scenarios should be devised. Such a method could compare the content found in the candidate areas (that show significant differences compared to the other chats) to the main topics that should have been reached in the conversations. If the concepts are semantically connected to these topics, then the areas are on-topic and should be considered creative. Otherwise, their content is off-topic and the areas may be simply ignored.

To demonstrate the viability of this method, [Chiru and Rebedea \(2017\)](#) applied the developed application on a subset of the corpus of chat conversations carried by senior Bachelor students involved in the CSCL task presented in a previous section. The dataset consisted of 25 similar chats, having in total 82176 words in 8798 utterances, with a vocabulary size of 5948 distinct words. In this research, an idea was considered to be a specific concept, which can be expressed by a word or a group of semantically connected words (the lexical chain of that word). To enable the detection of creative ideas, first the vocabulary of the entire dataset (containing all the ideas from the chat corpus) was extracted, along with the words' frequencies considering all the chats from the corpus.

Once all the ideas (concepts) in the corpus were identified, the system tracked their developments, the reactions they attracted and the conclusions that were drawn based on them and each utterance was labelled according to its type. Then, starting from the previous analysis, a second part of the application was built, which proposed a model for the evaluation of the participants' typology using the labels of their utterances and affective factors (e.g., if a participant is negative or positive throughout the conversation). This part of the application was built based on the premise that group constituency (participants' typology) is an important factor in developing creative conversations and that the outcome is also influenced by emotional/affective factors. Thus, the authors considered that knowing what kind of participants lead to different creativity levels might be important and devised a way to visualize each participant's typology.

Lost Ideas Identification

Lost ideas are the rare concepts that were found in only a small number of chat conversations. From the vocabulary, the concepts that were found only once were kept for analysis as candidates for lost ideas. This can be considered as a hapax legomenon for the concept space created from the entire corpus of conversations. To filter out the off-topic content from this list, the authors verified if the utterances where they were found contained (or not) other on-topic concepts. If these utterances had on-topic content, the concepts were kept and labelled as lost ideas. Otherwise, the rare words were labelled as off-topic, and the corresponding utterances as well.

This approach could have been extended to other rare words, with a larger appearance frequency, but, in the present context, this already led to a large number of concepts labelled as lost ideas (161 different concepts). Most conversations from the corpus contain lost ideas in about 1.5%–2% of the total number of utterances, with only a few conversations (4 out of 25) having a larger percentage of lost ideas (more than 4% of the total utterances from these 4 chats contain lost ideas).

The application shows each rare word that was found and was labelled as a lost idea and the user has the possibility of selecting the ones that (s)he is interested in. When a selection is made, the application shows the name of the chat in which that word was found, the participant who uttered it and the content of the utterance (see [Fig. 3](#)).

New Ideas Identification

New ideas are represented by concepts or combination of concepts with high frequency in a small number of chats. Thus, candidate concepts for new (creative) ideas were the ones with a frequency larger than the chat average, but that appear only in a small number of chats. Since these new ideas are interesting to be captured (from a creativity point of view), for each candidate utterance, the system extracted the pattern involving the concepts of interest, in order to verify if similar situations were also present in the other chats from the corpus. Thus, a window of variable length was considered involving the co-occurrence of relevant concepts (*concept_1* [*] *concept_2*) and consisting only of nouns and adjectives and then the utterances from all the chats from the corpus were investigated to see if they contain any such patterns, with a maximum deviation of a word (added or missing).

Using this methodology, the application was able to identify 95 patterns for new ideas, which were used afterwards to extract 2258 utterances from the corpus that matched at least one of the patterns. Out of the 95 patterns, 82 consisted of unique combinations of concepts, while the rest (13) had the same combination of concepts as one of the 82, but with different window sizes (different number of words in between the concepts). The window sizes varied from 1 to 9 words between the two concepts representing the pattern. The average window size for the identified patterns was 2.93 words, while for the utterances extracted based on them was 2.79 words, which means that, in average, the concepts investigated were separated by 3 other words. The number of new ideas was in most chats below 40% of the total number of utterances, with most conversations containing new ideas in about 20% of their utterances.

The application displays similar information as in the case of the lost ideas, as shown in [Fig. 4](#).

One of the authors' objectives was to determine whether the creative ideas detected automatically in chat conversations using this method are linked to the conversations which have a better general assessment from human tutors (which are domain experts). Thus, they verified whether the number of creative ideas (the sum of new and lost ideas) identified by the application in a chat can be considered as a proxy for a good quality conversation as assessed by tutors that take into account several different factors, including the content and the quality of the collaboration ([Trausan-Matu et al., 2014](#)). To this aspect, they computed the correlation

Figure 3 The display of lost ideas in the corpus of chat conversations.

between the number of creative ideas identified in a conversation and the quality score for that chat, as it was evaluated by domain experts. This test showed that this correlation is very high ($r = 0.74$), close to the inter-rater agreement scores on chat quality ($r = 0.86$), suggesting a strong connection between the detected creative ideas and the manual assessment of chats by the domain experts.

Identification of Ideas and Reactions

In addition to the creative ideas identified using the methodology presented above, [Chiru and Rebedea \(2017\)](#) also defined another four utterance categories, to be used in the evaluation of the creativity of individual participants: *reactions* (approvals, disapprovals or continuations of previously stated ideas), *conclusions* (discourse markers that are specific to conclusive utterances, such as *so*, *in*

Figure 4 The display of new ideas in the corpus of chat conversations.

conclusion, or to *sum up*), *developments of conclusions or ideas* (if the previous utterance contained on-topic concepts, its development should also contain words from the same semantic field), and *ignored utterances* (off-topic content and social noise, usually present at the beginning and ending of each chat).

Participants Analysis

Once each utterance was classified in one of the five classes from the above list, the system used these labels to evaluate in which typological category each of the chat participants might fit. This analysis is based on the belief that productivity in interactive groups is influenced by the participants' opinions regarding how they are perceived by their peers. Thus, the participants were evaluated in terms of their *leadership*, *development* (providing ideas related to the debated subject, but without introducing new concepts), *innovation* (bringing new concepts into the conversation), *negativity* (being against the ideas proposed by the other participants and endorsing this position with valid arguments), and *conclusive* (being the one drawing the conversations' conclusions) skills that they proved to have in their utterance. A participant received leadership points for having the most ideas about the debated topic, for managing to convince the others that the ideas in which (s)he believes are the best or for having her/his own ideas approved (or at least not disapproved) by the others. The off-topic utterances and the ones that did not contain anything meaningful to the topic of the conversation were clustered in another class – *others*.

Since the system was unable to (automatically) determine the relevance of a significant part of the utterances from the chat discussions' dataset, the *others* class contained the highest percentage of utterances (21% of the whole corpus of chats). From the identified skills, the highest score was received by the *development* category (20.5%), which is somehow expected as, during their undergraduate studies, the students are prepared to solve different problems, which involves reasoning and developing ideas given by a supervisor (which in this case, were the teachers). The next highest score typology that was present in the chats was *negativity* (19.5%), this fact being explained by the imposed topic of the chats: the students were asked to find the flaws of different technologies and, after that, to find a way to overcome those problems. Thus, in this context the *negativity* typology is influenced by and can be easily linked to the divergent step in the collaborative task at hand. *Innovation* (18.5%) was the subsequent typology, considering the obtained scores, and again this might be influenced by the nature of the conversation, that pushed the participants into thinking about various problems and solutions for them. An alarming low representation in the chats was seen for the *leadership* skills (5.5%). This low value might be partially explained by the fact that they had to work as a team to solve the task and there was no need for any participant to take the lead in the conversation. However, the low value should be an alarm signal, showing that during Bachelor studies, the students are not encouraged enough to exercise this kind of skills.

For each of the selected chats, the developed application displays one chart that has the participant's name on the horizontal axis and their percentages for the different typology types on the vertical axis, as shown in Fig. 5.

Figure 5 The display of participants analysis in a chat conversation from the corpus.

Figure 6 Two chats with different degree of inter-animation.

Results and Discussions

Discourse creativity is very complex and difficult to determine automatically. The tools presented in this chapter can be used by researchers and teachers to analyze chat conversations with multiple participants engaged in CSCL tasks in order to automatically determine some creative aspects, such as polyphonic discourse, inter-animation of ideas in a single discussion, or creative (lost and new) ideas by considering a larger dataset of chats on the same topic. PolyCAFe can be used for analyzing chat conversations to identify the main topics of the conversation, second voices (as discussed and shown in Figs. 1 and 2 above), and inter-animation of ideas starting from the polyphonic model. For example, in the chat from the top of Fig. 6 there is a greater degree of inter-animation than in the bottom chat. However, the assessment of creativity is performed by the user, either a researcher or a teacher, using the facilities of the developed tool. On the other hand, the corpus-based analysis of chat conversations provides an automated method to detect creative ideas in a conversation by comparing it with the utterances from several other chats having the same discussion topic.

The presented corpus-based analysis of creativity in chats has been fully automated for processing chat conversations with multiple participants engaged in the CSCL task discussed in this chapter. The developed tool can detect creative ideas in a conversation by analyzing a large corpus of chats that have the same topic, consisting of several groups of students working on the same CSCL assignment. Starting from the idea that creativity in language and discourse ought to be reflected by the differences in the participants' discourses and lexis, the tool analyzes the usage of rare relevant concepts throughout the entire corpus. These rare concepts are considered creative, as they are an intentional deviation from the standard concepts debated in several different chats from the corpus.

The tool and method of analysis described in this chapter make use of a corpus of similar texts to compute insights related to the concepts that are on-topic, but appear very sparse in the corpus, as compared to concepts that are more popular in the dataset and thus cannot be considered creative. This shows that discourse creativity can be automatically detected by analyzing the differences between discussions (creative ideas) and excluding similarities (regular/frequent ideas).

When investigating the creative ideas identified by the application, it is important to study the number and distribution of creative ideas in the entire collection. This can be seen as a quantitative indicator, as only a limited number of chats should be highly creative (e.g., contain a large number of creative ideas). Looking at the number of lost and new ideas in all chats from the analyzed corpus, it can be seen (in Fig. 7) that the distribution of creative utterances follows closely a slightly positive skewed Gaussian

Figure 7 The distribution of the frequency of lost ideas (A) and new ideas (B) in the entire corpus of chats.

distribution, highlighting that most conversations have a rather small number of creative ideas and only a limited percentage of the chats are more creative with regard to the number of discovered creative ideas.

The main difference between lost and new ideas is that the former are concepts that are related to the topic of discussion and were brought to the discussion by the participants, just to be either ignored or not accepted by the group. This means that either the students did not fully understand them, or they were not considered relevant for the debate. At the same time, the new ideas discovered by the application share important information about the connections between different concepts made by students, based on the learning materials. Further analysis of the new ideas discovered in the chats highlights that they were well connected with the conversation's-imposed topic of debate, which suggests two points:

- The developed application can be used to identify and extract patterns that are relevant for the topic of debate (the patterns capture relevant information from the text).
- As a large majority of the discovered new ideas are on-topic, the students followed in general the assigned topic for debate, without concept drift or abusing on off-topic talk.

A manual inspection of the new ideas identified by the system can also bring information about concepts that were not well understood by the students, as they are not connected to any other concepts in any analyzed conversation. For example, [Chiru and Rebedea \(2017\)](#) learned that the concept "wiki", which was one of the most relevant topics for the debate, was not found in any of the discovered patterns forming new ideas. This means that the students have not connected the "wiki" concept to other relevant concepts, showing that either they had difficulties in understanding the concept or in finding its proper relationships with other concepts relevant for the task. On a similar note, the frequency of the patterns in which different concepts were found might reflect the students' position regarding a preferred solution for the task at hand, when multiple choices are available. In the presented dataset, this examination showed that students were prone to consider that a *blog* combined with an online *forum* are the best instruments for information sharing and collaboration in a large company.

At last, some deeper insights were searched on the correlation between the number of creative ideas in a chat and the quality scores assigned by domain experts regarding the content of the discussion and the collaboration quality. An important observation is that the number of lost ideas is better correlated with the tutors' score on content ($r = 0.71$) than the number of new ideas in a chat ($r = 0.58$). On the other hand, from the collaboration point of view, new ideas achieve a higher correlation ($r = 0.81$) than lost ideas ($r = 0.58$). Thus, even though lost ideas are concepts which were not fully investigated in the chat, the fact that they were present only in a small number of chats indicated that the participants to those chats posed problems that the others were not aware of (or did not consider them to be important), suggesting a better understanding of the concepts and thus leading to a better evaluation by the tutors with regard to the content quality of the chat. The other point that was observed (high correlation between new ideas and collaboration) was somehow normal, being supported by the fact that in order to become a new idea, a concept must be intensely debated within the chat, which most of the time required the involvement of multiple participants, and thus, collaboration.

Conclusions

This chapter presented how creativity can be supported and detected in CSCL chats. Several methods and software tools were described that may be used for determining some creative aspects from chat conversations. One of them was PolyCAFe, which was designed to support researchers and teachers in analyzing CSCL chat conversations with multiple participants to understand the most important concepts in the discussion, potential creative ideas, inter-animation of ideas, and the overall quality of collaboration. The second application was a corpus-based tool for extracting creative ideas and the typology of chat participants starting from these ideas/concepts. This program requires a large collection of chats that have the same topic and uses statistics computed on the entire dataset to identify rare concepts and co-occurrence of concepts.

Software tools that can identify creative elements in texts and conversations automatically, or just support the user in a semi-automatic analysis, have a wide range of applications. This list includes but is not limited to support in brainstorming sessions, helping writers in search of inspiration for the right wording, automatic essay grading, or generating interesting expressions in natural language generation systems. However, in order to reach such goals, it is still needed to improve the methods for detecting utterances that are on-topic and how these utterances are connected with the proposed subject of the conversation. This way, further research will be able to provide a more complex analysis of creativity and to find more interesting information that, for the moment, remain hidden in the text.

The presented creativity-based method for classifying participants' utterances into different categories (e.g., ideas, reactions) and for defining participants' typologies starting from them can also provide an initial step for a better-informed group formation for CSCL tasks that considers the creative typology of each participant. This approach might also be used to support the analysis of collaboration/communication practices and thereby the provision of more adaptive external collaboration scripts.

In the end, the presented corpus-based application might also help Veale in his quest for retrieving creative (fresh or unusual) expressions that have the same meaning as the query ([Veale, 2011](#)) or the researchers investigating how people decide the choice of words when making up a novel noun-noun compound.

Introduction

Technology has revolutionized gaming, and now people play more games than ever. Digital gaming technologies are ubiquitous and abundantly available, being both a feature of digital communication media—such as smartphones—and, in themselves, a forum for digital communication. Because of the relative novelty of this condition, it is still unclear the magnitude of the psychological and cultural influence that easy access to digital gaming technology will have on society. There are, perhaps, causes to fear, as digital isolation and disconnection are becoming known as harmful consequences of engaging with this technology; there are also reasons to hope that this technology will provide an enduring benefit to humanity, especially demonstrated in the observation that there are already early signs of the capacity for digital gaming technology to significantly facilitate and activate creative engagement.

The purpose of this article is to articulate multiple frameworks for understanding how the concept of long-term engagement with play, games, and gaming (that is to say, playing games) can provide a broad vantage to think about the creative benefits of these activities, and, more specifically, the creative benefits of digital gaming in the modern world. The first section will present a historical discussion of the theory of play culminating in discourse about modern efforts exploring the benefits of gaming and the extent to which current research can illuminate a potential overall benefit to. This discussion will also focus on the extent to which the effect on creativity is demonstrative of more limited positive effects on cognition, emotion, social interaction, and motivation.

Then, drawing from the logic of play theory—most directly, from Huizinga's (1938) fundamental observation that games will, at the most basic level, influence the *self* and *society*—the discussion will draw from extant theories of creative behavior to articulate two complementary means by which to conceptually model the positive effect of video gaming on specific types of creativity: the first focusing on the theory of personal creativity; the second focusing on the theory of collaborative creativity. Each of those sections will describe how the theory provides insights about current research, culminating in suggestions for potential areas of future study.

From Video Games to Creativity: Gaming, Play, Costs, and Benefits

Games and gaming have increasingly advanced to the forefront of many peoples' lives. This is seen clearly in the spectacular rise of video gaming in recent history. Granic et al. (2014) pointed out that by the end of the first decade of the 21st century, more than 90% of children and adolescents had indicated that they played video games, contributing to a titanic \$25 billion industry that has overtaken forms of entertainment based on older technologies. Digital gaming has emerged as a social, cultural, and economic juggernaut, pervasively influencing the landscape of daily experiences.

Trends in the cultural and technological evolution of video gaming now appear quite quickly and tend to be vigorously disavowed in the aftermath. For example, a recent craze for Fortnite (see Lindberg, 2018 for an account) has cooled, and gamers are entering into a new epoch of eSports with the recent expansion of interactive platforms like twitch.tv (see Lecourt, 2018 for an account). As time passes, these developments, like many before them, will seem quaint and dated. But invoking this sense of impending obsolescence is, in fact, the point: It is precisely from knowing that games like Fortnite and gaming platforms like twitch.tv will be innovated, altered, rebranded, and possibly overtaken by competitors that offer the tools to consider the more salient historical, social, and psychological dimensions of gaming.

That is to say, apprehending the transient nature of games can enhance understanding of the enduring nature of play. Yesterday's *Royal Game of Ur* (see Scott, 2017) may have given way to today's battle royale-styled digital competitions, but players never seem to be tired of seeking the next new game. And, here, there are tangible reasons to believe that this understanding of inherent transition is a valuable perspective to have: Consider, by way of example, the legacy of the Nintendo Corporation, evolving as it did over a period of more than 100 years from the production of handmade paper hanafuda cards during the Meiji era to its current state as a leader in the development of digital gaming technology (see Caruso, 2014 for discussion).

It was Johan Huizinga who, in his (1938) book *Homo Ludens*, first critically examined games and playful activities from a broad variety of cultures and historical sources available to him to get an understanding of play and the extent to which it permeated

society. Huizinga came to believe that, above all other activities, play was the essential element of human culture; in his words, he understood “play” to be

the accompaniment, the complement, in fact an integral part of life in general. It adorns life, amplifies it, and is to that extent a necessity to the individual—as a life function—and for society by reason of the meaning it contains, its significance, its expressive value, its spiritual and social associations, in short, as a culture function (1938, pg. 9).

Huizinga took the role of play in human experience to be vast and expansive, encompassing cultural domains inclusive of the sacred, the mystic, the mysterious, and also those derived from ordered principles of social engagement: law, war, academic debate, poetry, art, and even, by way of entropy, politics. For the most part, Huizinga believed play to be a benefit to humanity, especially in spiritually ascendant esthetic experiences, as in poetry, music, and the visual arts (Huizinga, 1938, pp. 158–169).

Later, scholars of play, Roger Caillois among them, would not always paint such a rosy picture. For Caillois, play had descending, negative aspects as well. Play, in his estimation, did not contribute to sacred mystery, but instead exhausted it; furthermore, play was unproductive and contributed to “pure waste: waste of time, energy, ingenuity, skill, and often [...] money” (Caillois, 1958, pp. 5–6). Each of his four types of play—agon, alea, mimicry, and ilinx—was associated with a type of “corruption,” such as “violence” in games taking the form of agon, “superstition” in alea, “alienation” in mimicry, and “alcoholism” in ilinx games (Caillois, 1958, pg. 54).

More broadly with respect to the issue of corruption, Caillois presaged not only the potential for the influence of the “real world” to subvert play but also the conditions under which play would be employed to negative consequence:

Corresponding to each of the basic categories there is a specific perversion which results from the absence of both restraint and protection. [...] [T]he tendency to interfere with the isolated, sheltered, and neutralized kind of play spreads to daily life and tends to subordinate it to its own needs, as much as possible. What used to be pleasure becomes an obsession, and what was a pastime is now a passion, compulsion, and source of anxiety.

Caillois (1958, pg. 44)

And, indeed, in the wake of the intense rise of video gaming culture, it is not difficult to find real challenges very much like these facing a new generation growing up immersed in modern gaming technology: issues of gaming addiction, loneliness, and isolation amplified by the capacity that these games now have to absorb players’ lives in anxious compulsion (as in Stockdale and Coyne, 2018).

For this reason, there is an awareness of the potential costs of long-term engagement with video games that informs contemporaneous research into the psychological effects of gaming on individuals and social groups. Furthermore, there is an obligation, in light of those costs, to articulate the benefits of deep engagement with gaming. Granic, Lobel, and Engels, whose (2014) article was a direct attempt to categorize the type of benefits inherent to video gaming, framed their need to explore the topic with the argument that “in order to understand the impact of video games on children’s and adolescents’ development, a more balanced perspective is needed, one that considers not only the possible negative effects but also the benefits of playing these games” (2014, pg. 60).

Starting from this question of the benefits of video gaming, Granic et al. (2014) were able to find evidence in support of multiple kinds of positive influence of video gaming: those being (1) cognitive effects, (2) social effects, (3) emotional effects, and (4) motivational effects. Within each category of effect, the findings of one or more empirical studies cited by the authors were demonstrated as an outcome, such that an aggregate group of effects was formulated by convergence of multiple sources. In this way, for instance, the cognitive benefits of gaming were composed of influences on spatial reasoning, visual processing, attention, and problem-solving skills. Likewise, the effects of video gaming on emotions were conceptualized as improvements to mood and satisfaction, as well as facilitation of the flow experience. On reflection, Granic et al. (2014) found themselves to be “particularly inspired by the potential that these games hold for interventions that promote well-being” (2014, pg. 71).

As researchers begin to conceive of the benefits of gaming in the empirical sense, the research started connecting more deeply to a theoretical understanding of the creative nature of play. It was in the character of this type of effort that Jackson and Games (2015) integrated their own prior research findings into the framework of benefits proposed in Granic et al. (2014); they described a more fundamental basis for the canons of evidence promoting the benefits of video gaming: These benefits were, across all four previously identified categories, indications of a positive influence on the creativity of gamers. In their words, Jackson and Games (2015) identified creativity as a summary benefit of gaming “mediated [by] beneficial cognitive, social, emotional, and motivational effects” (2015, pg. 30).

Bowman et al. (2015) advanced a similar line of reasoning, effectively tracing a history from Huizinga’s work through the study of play to the incorporation of the topic into the study of creative thinking skills. They then elaborated their position by reframing the causal model, postulating that “part of the reason why play is so successful at stimulating creative thinking is because play is a creative process in and of itself” (2015, pg. 43). For them, video games represented a new paradigm in the study of creative play, in that, unlike games that had existed in prior eras, video game technology provides spaces that enable multiple game types in a rich interactive environment that could not have existed more than a few decades ago (2015, pp. 47–54).

If a benefit of gaming is increased creativity—and there is a growing body of evidence to support this—what comes next? How, does the procreativity perspective inform the role of modern digital gaming as a reasonable investment of time and attention, above and beyond the simple joy that healthy play can afford?

Perhaps the most useful vantage is the most theoretically parsimonious: That, following the most fundamental insight of [Hui-zinga \(1938\)](#), scholarship should primarily cultivate understanding for the principle participants of play, meaning a direct, mindful focus on how play influences the creativity of the *individual* and larger *society*. The following sections will include a discussion of the form, context, and background of personal and collaborative models of the creative benefit of video games and will highlight the potential contributions of creativity theories as they apply to the individual and to the society, both in organizing the grounds of evidence into larger constructs for analysis and in proposing avenues for further investigation.

Gaming as a Benefit to the Individual: Personal Creativity

In his article, *Personal Creativity*, Mark [Runco \(1996\)](#) described a conceptualization of creativity applicable to individual creative behavior, manifested as desire to “transform the objective world into original interpretations, coupled with the ability to decide when this is useful and when it is not” (p. 4). Transforming (in other words, adapting or accommodating) and interpreting ideas and experiences held a central place in Runco’s theory, driving the mindful discretion, as well as directing the intentions of creative individuals. This type of “idea transformation” was associated with problem-solving and problem identification and a state of deep immersion in a project ([Runco, 1996](#), pg. 5).

Embedding Runco’s construct of idea transformation and the language of personal creativity into the discourse concerning the creative benefits of gaming technology generates a modified perspective that more deftly incorporates [Granic et al. \(2014\)](#) evidence of benefits to cognition and emotion more seamlessly with extant creativity research. The indicative label “transformation” is used by scholars to typify a variety of mental capacities, many of which characterize a high degree of personal interaction with ideas, incrementally forming the substance and foundation of knowledge acquisition. [Alexander et al. \(2011\)](#) situated transformation as an essential component of their process-based operationalization of higher-order thinking skills, defined as “Mental engagement with ideas, object, and situations, in an analogical, inductive, deductive, and otherwise transformational manner that is indicative of an orientation toward knowing as a complex, effortful, generative, evidence-seeking, and reflective enterprise” ([Alexander et al., 2011](#), pg. 53).

Here, among the constellation of cognitive skills that constitute higher-order thinking, transformation is contributory to a “deep processing” approach, one that extends—very much in accord with Runco’s position in the theory of personal creativity—beyond surface-level procedures, and into efforts to “understand meaning, question the author, justify evidence, and relate material to personal experience” ([Alexander et al., 2011](#), pp. 52).

But does the available evidence support the inference that cognitive transformation might help explain the positive influence on creativity of video gaming? This was an issue broached, if obliquely, in one of the few early studies empirically investigating the potential benefit to creativity of video gaming: [Jackson et al. \(2012\)](#) gathered responses from gamers to figural and verbal creativity tasks and analyzed those correlations for a pattern of relationship. They discussed in their conclusion the possible effect of “computational thinking,” defined therein as a “broad range of mental tools and concepts [...] that help people solve problems, design systems, understand human behavior, and engage computers” (p. 374).

While their tone was tentative—an especially salient point, given that their findings were based on correlational observations—this group did nominally credit that “computational thinking is related to creativity, and that together they facilitate interest and performance in the virtual world—the world of video games” ([Jackson et al., 2012](#), pg. 374). Their description of “computational thinking” relates to the constituents of “deep processing” because computational thinking has been demonstrated on other occasions to closely relate to creativity through cognitive transformation ([Veale et al., 2006](#)). However, given the nature of the findings, perhaps the best framework for understanding would be to consider both potential components of a more complex model.

And so, if the current evidence can support that video gaming benefits transformational thinking, what value might be derived from the elaboration? This question returns the discussion to an examination of the practical dependencies of higher-order cognition illuminated by [Alexander et al. \(2011\)](#) and raises the issue of the emotional benefits as a partial contribution to creativity enrichment driven by enthusiasm for video gaming.

In [Alexander et al. \(2011\)](#), strong statements were made underlining the perspective that experiential interactions amplify their meaning and long-term utility when a person employs higher-order thinking, but that higher-order processes do not occur on their own or without sufficient reason—that they can emerge only when the developmental, social, and, most importantly, dispositional characteristics of the individual align in purpose to promote higher-order engagement, transformational thinking, and deep processing. By highlighting disposition, [Alexander et al. \(2011\)](#) were, in essence, encouraging the notion that individuals must find an emotional connection to a topic, that they must have a “dispositional orientation,” to invest in higher-order thinking: In fact, a sizable portion of their writing was devoted to discussing the challenges of appealing to the emotional and dispositional orientations of individuals, examining as they did the dimensions of “what,” “who,” “where,” and “when” (2011, pp. 56–76).

Runco viewed emotion to be a necessary characteristic of personal creativity; “Creativity will not be well understood just as a cognitive mechanism; it is also emotional or affective” ([Runco, 1996](#), pg. 23). However, Runco struggled to offer a definitive account of the effect of emotions, which he presented as “extracognitive bases” on personal creativity; instead he posited a scatter-shot of possible influences, ranging from the effects of autonomy and nonconformity to mindfulness and, at the extreme, to

deviance (pg. 23). He proposed that transformative interpretation depended on a person's emotional perspective, that "problematic" circumstances would create "anxiety," complicating interpretation, while a contrasting "enjoyable" view of a situation would not interfere, being instead thought of as a "challenge," and would thereby better promote transformative thinking (Runco, 1996, pp. 7–8).

Jackson and Games (2015) provided a direct argument for the effect of positive emotions on creativity: Video games are gratifying, they improve mood, they aid in relaxation, and diminish anxiety, all of which contribute to a net facilitation of creative conditions, such as inspiration and challenge (2015, pp. 24–25). In addition, they stated that video games enhance creativity through their ability to induce a "flow state" (Jackson and Games, 2015, pg. 24), which Bowman et al. (2015) described as "improved focus on the task, a sense of active control, the merging of action and awareness, a loss of self-awareness, a distortion of the experience of time, and [...] experience [of] the task as being the only necessary justification for continuing it" (Bowman et al., 2015, pp. 45–46). That the flow state can augment individual creative thinking is uncontroversial in the field of creativity research, and its effectiveness in this area is well documented (Granic et al., 2014, pp. 6–7).

So, to offer a brief summary, there is some justification based on extant research for taking up the perspective of personal creativity as a frame to evaluate the benefits of creativity afforded by video gaming through the lens of idea transformation and the uniquely motivating power of the video gaming experience. Additionally, based on the theory of personal creativity, there is reason to believe that these aspects of creative benefit—the cognitive and the emotional—are, even if separable in the abstract, inseparable in practice, as positive dispositions lay the necessary groundwork for deep processing. This enriches understanding by more concisely operationalizing (1) the overall character of individual creative outcomes expected from video gaming, (2) the type of thinking skills that might best benefit from video gaming, and (3) the vital import of emotion, and most especially flow, in affecting dispositions such that individuals will want to engage in creative cognition.

Where might further research go from here? An obvious direction, as the personal creativity interpretation of the creative benefits of video gaming is, at present, not yet verified by experiment, would be to explore the components of the theoretical model. One avenue might be to use empirical methods to structure a mediational model to assess the effect of flow on transformational thinking on individuals with contrasting histories of video game use. An alternative approach might be to use qualitative methods as a means of capturing a sense of the flow experience among a group of video game enthusiasts and, moreover, to relate those experiences to how those individuals use transformational thinking—in what social contexts and referencing what domains. One might also make use of a mixed-methods approach, starting with qualitative research investigating the expression of the flow and idea transformation phenomena, and complementing that canon of evidence with quantitative data looking at correlations and linear relationships among each construct.

Gaming as a Benefit to Society: Creative Learning Environments

In his article *Paradigms in the study of creativity* Vlad Petre Glaveanu in 2010 set forth the principles of a perspective on creativity that positioned the sociocultural character of the creative endeavor as a central focus. Proposing an alternative to the individualistic attributions of creativity and creative potential that have long dominated the field, Glaveanu instead recast creativity as an inherently collaborative act that was contextually sensitive, dialogic, and cocreated in the collective efforts of groups of people, very much in agreement with the constructivist reasoning of educational philosophers like Lev Vygotsky (Glaveanu, 2011, pp. 480–481). This "We paradigm" of creativity proposed an integrative account of creative behavior, most especially in emphasizing the mediational role of cultural artifacts—psychologically profound physical and conceptual creative products—through which societies expressed and accumulated their experiences over time (Glaveanu, 2010, pp. 84–86).

Glaveanu's insight concerning the nature and significance of the cultural mediation of conceptual artifacts encourages a divergent perspective with regard to interpreting the evidence provided by Granic et al. (2014). The shift involves understanding the social and motivational benefits of video game interactions and their contribution to creativity, as a positive influence transmitted throughout a social group. This invokes, too, the notion of how developments in the application of sociocultural theory can inform the practical realities of employing video games in the educational context—"gamifying" learning (Deterding et al., 2011)—as a medium for meaningful influence on the creativity of young people. For, as Glaveanu (2010) elucidated, constructivist theories and sociocultural formulations have already been well represented in the study of certain topics in the learning sciences. As Jackson et al. (2012) and Bowman et al. (2015) demonstrated, there is already a willingness to make use of educational gaming platforms as a tool for enhancing creativity.

First, though, to make any use of the idea of Glaveanu's (2010) mediational tools as a means to analyze the social aspect of the creative benefit of video gaming, there is a need to demystify the construct. Egan (1997) offered one thoughtful method of doing so: That the essence of games, narrative, and the imagination, the tropes that undergird how individuals come to understand wonder in the world, are, in themselves, these mediational tools (1997, pg. 5). Derived from stages of development and the internalization of cultural literacy, Egan (1997) conceptualized a number of these "cognitive tools" of the imagination—binary structures, fantasies, heroes, extremes of reality, collections, anthropomorphism, and curious anomalies, to name a few—and ordered them in a sequence, progressing from basic somatic understanding, through mythic and romantic understanding, to a sophisticated theoretical or ironic understanding of the world. In this way, as Egan (1997) posited, mediational tools become simultaneously the products of the individual imagination and cultural mediators of learning, as recapitulations following the story form embedding a "cognitive tool" are thought to be facilitative of salient integration of conceptual knowledge.

Following Egan's (1997) interpretation, then, mediational tools bind up the social and creative influences of video games into a reciprocal relationship, generating an additional layer of explanatory power to texture the social benefits of video gaming to the creativity of social groups. Take, for example, Jackson and Games's (2015) analysis of the social role of the different genres of video games, wherein they struggled to explain the seeming paradox of violent video gaming as a positive influence to the prosocial behavior of young people, coming only to the conclusion that the collaborative quality of play would mitigate the negative effect of the violence (2015, pp. 23): Through the lens of mediational tools as they are used in video games, the effect would not be paradoxical at all; it would instead be considered the reasonable result of an act of collaborative creativity through which positive effects from violent video games would be an expected outcome of socially experiencing an archetypal "extreme of reality" (as in Egan, 1997, pp. 83–84). Thus, in this instance, the social benefit of gaming would not be in collaboration alone, but, would be, more finely conceptualized as an exemplar of interaction mediated by a known type of cultural learning tool.

As Egan (2005) argued, the real utility of mediational tools is to be found in applications that drive learning and motivation, particularly in educational environments. In line with this reasoning, Egan (2005) organized an instructional theory, the *Imaginative Education* method, based around incorporating these tools into classroom practice, and further exemplifying throughout his work the process of recapitulating components of knowledge through the captivating medium of mediational tools such that they might better engage the sense of wonder in the imaginations of learners and enjoin deep, creative thinking.

Taken into the purview of collaborative creativity, motivation is a topic with a great deal of conceptual interrelation to the social and creative benefits of video gaming. Sociocultural theory includes the concept of the "zone of proximal development" (ZPD), that "sweet spot" between challenge and frustration that contributes to the motivational benefits of long-term experience with video games (Granic et al., 2014, pp. 65–66). Thus well-crafted video games might occupy a central conceptual location of the ZPD in being just challenging enough to enjoy and motivate through continual engagement of those conceptual elements which were distant prior to the experience.

This idea finds resonance across scholarship relating video gaming, creativity, and the sociocultural perspective because an appeal to the effect of maintaining engagement in the ZPD can be seen in works describing the mechanism by which the creative benefits of collaborative creativity are to be understood (Glaveanu, 2011, pg. 48), and also, more precisely, in accounts in which the creative benefits of video gaming are conferred to individuals and groups of players (Jackson and Games, 2015, pp. 26–27). Indeed, so central to the notion of collaborative creativity was the topic of motivation that Glaveanu (2011) promoted it as part of the "new vocabulary" to understand creative behavior, one that was organized around the study of (1) ongoing interactions occurring via mediated contact, (2) the dimensions of socioemotional, motivational, and identity relative to creativity, and (3) the macrogenetic (socially and developmentally structured) aspects that influence daily creativity (2011, pg. 481).

In synthesis, Glaveanu's (2010, 2011) sociocultural theory of collaborative creativity enriches an understanding of the socially creative benefit of video gaming through the construct of mediational tools and, at the same time, situates the motivationally creative benefit of video gaming in the larger structure referencing the optimally challenging conditions occurring within the zone of proximal development. Here, Egan's (1997, 2005) work represents an instantiation of the sociocultural theoretical perspective, serving to unpack the historical, social, and developmental meanings of mediational tools, granting clarity in their constitution, and also in the prescriptive application of those mediational tools in learning environments as an effort to capitalize on their capacity to increase motivation by evoking wonder. This, by extension, would ameliorate difficulties with inert knowledge in the learning environment, modulating the challenge of deep conceptual learning. Evidence from both Granic et al. (2014) and Jackson and Games (2015) supports this sociocultural interpretation, both in articulating the social and motivational benefits of video gaming.

Future research guided by this theoretical framework might adopt an integrative approach to determining the culturally creative benefits of video gaming by examining the effect of mediational tools on the motivation of social groups. In a gamified learning setting, this might take the form of an educational video game with features drawn from the mediational and pedagogical tools of imaginative education. Assessment of outcomes could follow a mixed-methods approach, making use of participant interviews about creativity in the group, as well as self-report measures of creative engagement, response to creative environment, and intrinsic motivation. Alternatively, and more simply, a researcher might choose to investigate the effect of utilizing a single mediational tool on the creativity of a social group or organization, tracing, for example, how a creative group might structure binary opposites as they work through a problem together, or how, in constructing an audience, the group draws on experiences of extremes of reality. Such a study could be ethnographic in nature, entailing inquiry posed throughout the full arc of a creative endeavor, or it could be quantitative, contrasting influences across many social groups.

Glossary

Applied Evolutionary Epistemology The study of the units, levels, processes, and mechanisms by which (1) biological, (2) cultural, and (3) biocultural evolution occurs. See also (Gontier, 2012).

Archive The units of culture (ideas, processes, products; memes) *not* selected as canon, in a domain in culture. The equivalent (in biology) of dead or extinct lifeforms, or fossils. Over time, archived memes may become canon, just as extinct lifeforms can be recreated. Conversely, canonical memes can go archive over time.

Biological Evolution The operation of the evolutionary algorithm, resulting in units in biology surviving (the currently living units being ‘canon’), or, going extinct (thus becoming ‘archive’/fossils).

Canon Units of culture (ideas, processes, products) that are selected by the field, and are thus populous (or “viral”) in bioculture. The equivalent of living, surviving units in biology. Canonical artifacts exist as (external) *e-memes* in a domain, and as (internal) *i-memes* in the minds of those in the field. Canon is the complement of ‘archive’ in a domain.

Creative The standard bipartite definition of *creative* is a cultural artifact (a meme: an idea, process or product) that is judged *original and effective* (Runco and Jaeger, 2012), or *new and useful* by consensus of a field of experts for a domain in culture. The tripartite definition of creative is an artifact that is *new, useful, and surprising* (Simonton, 2012). See also (Kozbelt et al., 2010).

Cultural Capital Knowledge, information, skills, taste, and expertise possessed by an individual or group.

Cultural Evolution The process by which evolutionary algorithms (*macro*: variation, selection, transmission, and also, *micro*: selection, variation, transmission) results in units of culture (memes: ideas, processes or products) becoming canon or archive over time.

Culture Culture is composed of *domains of knowledge* (the sciences, social sciences, the arts/humanities/communication; also cuisine, clothing, transportation, education, architecture, etc.), and *domains* are composed of memes (units of culture, i.e., units of information). These include: ideas, processes, products. *Ideas* can include concepts, principles, beliefs, models, theories.

Processes include customs, traditions, social behaviors, algorithms. *Products* include words, sentences, languages, numbers, symbol systems, images, photographs, idioms, catchphrases, artworks, buildings, inventions, and any tangible cultural artifact.

Economic Capital Refers to ownership of—or access to—financial resources, or property, including intellectual property.

Evolutionary Algorithms A process such as Selection, then Variation, then Transmission of a unit. A process whereby units are (1) *selected* from a pool, then (2) *varied* (by combining parts of two or more existing units), and then (3) *transmitted* back into the “pool” or population of competing units in an environment, where natural, and/or artificial (intentional), sexual, or unconscious selection also operates, and deletes the less-well-adapted units. The gene pool in biology (in DNA) is analogous to the meme pool (ideas, processes, products) in culture; evolutionary algorithms operate on both pools, on different scales and levels.

Evolutionary Epistemology The study of how knowledge in cultural domains (scientific, artistic, technological) evolves via selection.

Habitus As described by Pierre Bourdieu, ‘a feel for the game’ developed over a lifetime of immersion in domains and fields. A *habitus* is shared (in fact, learned) among people of similar profession, ethnicity, nationality, education, social class, and religion (Bourdieu and Johnson, 1993).

Holon/Partons Parts which are also a whole. Systems are holon/partons, being composed of (smaller) holon/partons. These are governed by the three laws of holon/partons, in addition to any other laws, rules, codes, or forces which may also be acting upon them, such as the current disciplinary zeitgeist of the field for a domain in culture.

I-memes Mentally-stored information (internal culture), namely the units in a person’s memory that were once e-memes (external memes), that they have learned, internalized or otherwise mentally absorbed. Biological instincts are not considered i-memes on this view of culture, as instincts are algorithms hard-wired into the organism via DNA and epigenetics.

Internet Meme An (often humorous, or ironic) image with text-caption shared on social media, or videos and other media shared on the internet. Internet Memes are a very small subset of all cultural memes; namely, of all ideas, processes, and products.

Kuhnian pre-paradigm state The state that a field and domain is in, before the scientific units (fundamental particles), criteria, and key problems are determined for a domain of study; see Thomas Kuhn (1996).

Memes Units of culture: ideas, processes, products. These are structured as holon/partons. Memes are either internal, mental representations (i-memes) or external physical culture (e-memes).

Memeplexes Complex memes. The term is relative, because an idea such as ‘computers’, or ‘the universe and every thing in it’ can contain many complex ideas. A transmedia story is a memeplex, as is a religion, or even a Kuhnian scientific paradigm. A memeplex is also a holon/parton, a unit of culture, a meme.

Multilevel Selection Theory The scientific theory that selection (natural, artificial/intentional, sexual, unconscious) in evolutionary processes operates at the various units and levels of the biological holon/parton: genes, DNA, cells, organisms, groups, species, biospheres. MLS also applies to culture on the various units and levels of the holon/parton: letters, words, sentences, books; and scientific, literary, musical, and cinematic canon.

Problems Defined here in the broadest sense, as: wants, needs, desires, goals, tasks, or objectives. Problems can also include obstacles to these goals. Examples of problems include: surviving, reproducing (raising offspring), staying healthy and happy, and avoiding illness, injury, undesirable stress or boredom, and more.

Selection pressure Where units effectively compete with each other for finite resources (e.g. food, or human attention) in any environment, pressure causes some units to adapt (or they are adapted by intentional re-designers) and thrive, while others are forced out of the ecological niche and may go extinct, unless they become adapted (or are exapted) to another niche.

Social Capital Social networks, relationships or connections, or “who you know” within a field for a cultural domain.

Symbolic Capital Awards, or recognition such as senior guild memberships and honorary titles.

Technology Anything that is a *tool*—from a rock used as a hand-axe, to a computer mouse, or car; from a word or a language to a diagram or book; from a computer to an fMRI machine. All units in culture (ideas, processes, products; memes) are problem-solving (goal-attaining) tools, and thus are bio-cultural technology.

Memes: Tools/Technology/Culture

Memes are units of culture. They generally take one of three forms: ideas, processes, or products. Memes are technology, as they are tools used for solving problems. The word “problems” is here used in the positive sense of the term, namely goals, tasks, aims, objectives, urges, wants, needs, desires. Sub-problems also can include any obstacles to such goals.

Memes are the key subject-matter that scholars generally examine in scientific studies, including the study of creativity. Once a cultural product—such as a scientific model, an artwork, book, song, or invention—is judged by consensus of the field to be creative (i.e., original and effective), creativity scholars can investigate the processes or the events that caused the emergence of that creative cultural artifact.

Culture as Solutions to Problems

All memes (units of culture) are solutions. Some solutions are judged by the field as more original and effective than others. As an example, the mental model or (1) *idea* of Einstein's $e=mc^2$ equation meant that (2) a *process* of converting matter to energy could be predicted and controlled, and eventually resulted in (3) the *product* of the atomic bomb. Although nuclear weapons created new problems, in 1945 they ended World War II, saving millions of lives. Creativity also raises the question of values and ethics, since with life comes problems, and the values placed on resources by individuals and groups. Any technology may be used for good or for evil.

All domains in all cultures of the world are composed of memes. They are solutions informed by values. This problem-solution view of all culture is illustrated via selected examples in [Table 1](#).

Units of culture include (but are not limited to): numerals; letters of an alphabet; symbol systems; words; phrases; languages; scientific or mathematical formulae; cultural customs, traits, rituals, practices, behaviors, beliefs, concepts; games; jokes; poems; paintings; songs; dances; novels; nonfiction books; scientific models; newspapers; technological and architectural blueprints or maps; legal systems; construction tools; buildings; books; movies; television shows; videogames; comics; clothing styles; cooking recipes; foodstuffs; measuring instruments; white goods; vehicles; aircraft; weapons; fuels; urban myths; conspiracy theories;

Table 1 Some units of culture (memes: ideas, processes, products) as problem-solutions.

<i>Problem</i>	<i>Solution: The idea of</i>	<i>Solution: The process of</i>	<i>Solution: Products, such as:</i>
The desire to communicate (interact) verbally and aurally	Verbal utterances conveying meaning (communication)	Speaking; listening; using grammar and syntax, having a conversation, etiquette	Communication tools: Words, grammar, syntax, sentences, speeches, conversations, landline telephones, smartphones, video calls, the internet
The desire for written communication or interaction	Stored symbolic information (written symbols)	Writing, drawing, using a computer to transmit symbols	Written words, languages, diagrams, clay tablets, codexes, printing press, books, emails, web pages
The desire for expressive, aesthetic, and/or moral communication or interaction	Art forms, fiction storytelling, songs	Drawing, painting, sculpting, creating fiction, making: movies, novels, songs, dances, television shows, etc.	Drawings, paintings, sculptures, movies, novels, songs, dances, television shows
The desire to eat	Culinary arts	Cooking, making and using recipes	Recipes, meals, plates and cutlery, ovens, refrigerators, kitchens, cafes, restaurants, etc.
The desire for attack or defense	Weapons and shields	Weapon making, weapons training and practice	Clubs, spears, axes, shields, martial arts, guns, missiles, tanks, aircraft, bombs, armies
The desire for bodily protection from the weather or elements	Clothing	Designing and making clothing	Coats, shoes, pants, shirts, dresses, hats, clothes stores & factories, clothing fashion styles
The desire for travel (across: Land, water, air, space)	Transport, via animals or vehicles	Designing and making vehicles, repairing vehicles, taking journeys in vehicles	Vehicles: carts, bicycles, cars, trucks, buses, tanks, boats, submarines, trains, aircraft, spacecraft; fuels (petroleum, electric, solar); auto repair shops
The desire to understand, predict and control: Health	Medical science	Diagnosis and treatment of illness; medical drug tests; diets; exercise	Medicines, drugs, vaccines, diets, surgeries, surgical tools, hospitals, medical textbooks, gyms, educational courses
The desire to be informed, entertained, and/or educated	News, gossip, entertainment, education	Creating and consuming: news, gossip, entertainment, education	Newspapers, TV, radio and internet news programs, books, videogames, documentaries, etc.
The desire for sexual pleasure, fornication	Sexual intercourse, masturbation	Courtship, dating, sexual fantasies	Sex, contraceptive devices, pornography, prostitution, erotica, etc.
The desire to understand, predict and control: Energy, matter, information	Physics (as one example)	Physics experiments; Planned (controlled, predicted) subatomic particle collisions	The double-slit experiment; the large Hadron Collider; nuclear power plants, etc.
The desire to go to the moon	Space exploration/discovery	The Apollo space program	Computer microchips, spacecraft, spacesuits, freeze-dried food

religions; worldviews; Capitalism; Marxism; Freudianism; Darwinism; and machines such as the printing press, electronic computers, 3D printers, the internet, and the Large Hadron Collider. All are problem-solving tools, thus all are technology. All are memes.

Problems (i.e., Goals) Emerge From Life

As Sir Karl Popper (1999) and Brian Boyd (2009) have noted, problems emerge with life, and all life is problem solving. Problems can also be categorized using the six levels of Abraham Maslow's (1969) hierarchy of human needs (goals, problems). These can range from staying alive, healthy, and happy for as long as possible, to achieving self-selected goals of creative mastery of a domain in culture. Maslow's sixth level is "transcendence", via advancing a cause larger than oneself in any domain, and enjoying "peak experiences" or what Csikszentmihalyi (1990, 1996) termed the "flow" state.

Biological systems such as plants and animals modify, fill, and construct ecological niches. Like nature, culture abhors a vacuum; so creative people frequently find better solutions. As solutions, inanimate units of culture (memes) can fill, construct new, and also alter, cultural ecological niches. Entertainment media such as television, videogames, movies and music can also place their audiences in the flow state. Sometimes they contribute to the growth of the Creative Industries.

New problems can also be caused by advances in memes (technology): improved medical science has caused a human population explosion, while fossil fuels and overconsumption have accelerated global climate change. In turn such problems require new creative solutions, in an iterative spiral of cultural evolution.

Getzels (1982) showed that unsolved problems in a domain in culture are of three main types: "presented", where the field is aware of the unsolved problem; "discovered", where a creative person identifies a hidden problem; and "created", where the problem (or goal) is newly formulated by an individual or group.

A Brief History of the Domain of Memetics/Cultural Evolution

As with the domain of Biology prior to Watson and Crick's (1953) discovery of the structure of DNA, the domain of Memetics—as a science of cultural evolution—was in a Kuhnian pre-paradigm state prior to 2016, as the hard domain problems of the unit, the structure, and criterion of the meme remained unsolved.

Charles Darwin and Richard Dawkins made important discoveries in both biological and cultural evolution. Darwin (1871) observed that individual units of culture (words, and languages) evolve via natural selection, including their historical spread and extinction. The prospect of a true Science of Cultural Evolution was raised when Richard Dawkins' (1976) popular science book *The Selfish Gene* noted that units in culture evolve. Dawkins coined the term "meme" for units of culture, or:

"a unit of cultural transmission... Examples of memes are tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches... If a scientist hears, or reads about, a good idea, he passes it on to his colleagues and students. He mentions it in his articles and his lectures. If the idea catches on, it can be said to propagate itself, spreading from brain to brain" (Dawkins, 1976, p. 192).

Dawkins is here describing the spread of creative (i.e., new and useful) ideas, processes, and products. This transmission of units of culture (memes) in society can be viewed via Lasswell's (1948) 5-W model of communication (see Table 2).

Table 2 Lasswell's 5-W model of communication.

Question (Lasswell's 5 W's)	Element	Analyses
Who	The <i>creator (and/or) transmitter</i> of the message or information (i.e., the meme, or unit of culture)	Creativity studies; media ownership and control studies; Communication studies
Says What	The discrete transmitted <i>meme</i> /information/problem-solution (idea, process, product)	Creativity studies; comparative form, content, and (semantic and pragmatic) meaning analysis of the specific transmitted unit of culture
In Which Channel	The <i>Medium</i> (audio, visual, verbal, written text, film, television, book, academic journal, email, social media, painting, sculpture, invention, and so on)	Creativity studies; Media studies; Communication studies; Information Science and Technology; Arts/Humanities
To Whom	The unit's (the meme's) <i>receiver; the audience; the field</i> for a domain	Creativity studies; Audience studies; demographics
With What effect?	The <i>effect(s)</i> of the specific problem-solution (specific discrete meme, or unit of culture)	Creativity studies - is the unit then widely re-transmitted as canon, or ignored as archive? Why, or why not? Effects studies - how does the meme affect the behavior/experience of the recipient(s)?

Adapted from Lasswell, H., 1948. The structure and function of communication in society. In: The Communication of Ideas, Institute for Religious and Social Studies, New York, pp. 117–129.

Following Dawkins (1976), much was written on the nature of memes (see Memetics Bibliographies in *Relevant Websites*), with alternate terms coined as synonyms for “meme” including: “culturgen” (Wilson and Lumsden, 1981), “tème”/“treme” (Blackmore, 1999), “mneme” (Semon, 1921), “seme” (Buysens, 1943), “deme” (Situngkir, 2004), and “mind virus” (Dawkins 1991). From 1997 the *Journal of Memetics* was published but ceased in 2005 under criticisms that the field of Memetics had not yet scientifically identified the unit of culture, nor solved the measurement, criterion, or theoretical model problems. In 2008 a five-year study of Memetics commissioned by the US military’s DARPA (Defense Advanced Research Projects Agency) resulted in a 1680-page report reviewing the extant knowledge on memes, but did not scientifically identify or accurately define the unit of culture (see Finkelstein, 2008). DARPA’s aim with Military Memetics was to fight wars and terrorism at the level of ideas (what we can now view as Sir Karl Popper’s (1978) “World Three”) and mental processes (or Popper’s “World Two”) rather than in the external physical realm of bodies, bullets, bombs, and blood (Popper’s “World One”). A parallel body of research also exists on Cultural Evolution that is not published under the rubric of Memetics; Creanza et al. (2017) contains an overview.

A Solution to the Meme Puzzle

In a 2016 Ph.D. study, communication scholar J. T. Velikovsky proposed a solution to the structure and mechanisms of the unit of culture. Once the unit, criterion, and measurement problems of culture are resolved (via Systems Theory) the controversy around memes dissipates. The remainder of this article summarizes this new view of the meme, (the unit of culture), and *Creative Practice Theory* (Velikovsky 2016a,b), a twelve-stage algorithmic model of cultural evolution, synthesizing evolutionary systems models of culture by Darwin, Csikszentmihalyi, Gruber, Simonton, Bourdieu, Koestler, and Popper.

The Systems Worldview

Mihaly Csikszentmihalyi (1988) and Howard Gruber (1988) both called for and defined systems views of creativity. A landmark article on creativity by Hennessey and Amabile (2010) in *Annual Review of Psychology* also called for the Systems View—from culture, down through six major systems levels, to the neurological—to further illuminate the phenomenon of creativity.

Stated most simply, a system is a “black box” with algorithms (processors) inside it; has inputs and outputs; and the system is located in an environment, or biocultural ecosystem (Fig. 1).

Systems are made of energy, information and matter. *Natural*, organic, living systems (plants, animals, whole ecosystems) have different inputs and outputs to *artificial*, human-made, manufactured systems (machines, factories, vehicles, transportation systems, towns, cities). A beaver’s lodge and dam, ant’s nest, bee’s hive, spider’s web, and crows’ and chimps’ use of tools are natural technological artifacts; niche construction; or “natural” culture.

Systems also contain algorithms for processing or converting inputs into outputs, and to monitor, grow, and maintain the system. As biological systems, organisms are algorithms, being information, energy, and matter processors. Complex systems are composed of smaller systems, and are part of larger systems. Fig. 2 is a Systems View, from quarks to the multiverse.

Theoretical physicist David Bohm (1980) suggested that the scale of these units continues infinitely smaller (“downwards”) and larger (“upwards”).

If we begin with the “Person” system (center of Fig. 2), we see they are composed of smaller systems/units (including: 11 organ systems; 79 organs; 10^{14} cells; and so on). The person is also a part of larger systems and ecosystems (a local community; a legal state or province; one of 195 current world nations; a biosphere; a solar system; a galaxy; and so on). Each system on each level (as indicated in the diagram) is a holon/parton.

Figure 1 A system in an environment.

Figure 2 A systems view, from quark to multiverse. Adapted from Velikovskiy, J.T., 2016a. The holon/parton theory of the unit of culture (or the meme, and narreme) in science, media, entertainment and the arts. In: Connor, A., Marks, S. (Eds.), *Creative Technologies for Multidisciplinary Applications*, IGI Global, New York, p. 211.

Systems as Holon/Partons

A holon/parton is a whole unit, that is also a part of a larger unit. It is a whole and a part at the same time. The three laws of holon/partons—which are also laws of physics—are that they each:

1. Compete, and/or co-operate (collaborate) with other units on the same level; and
2. Control and command the units on the level “below”; and
3. Integrate into the larger system on the level “above”, of which they are a part.

On this view, humans are emergent physico-chemico-bio-psycho-socio-cultural systems. In Systems Theory, Systems (and Complexity) Science, Systems Philosophy and Systems Thinking, the concept of “emergence” means that the properties of the whole unit cannot merely be explained by the sum of its parts. Consilience, the vertical integration of the sciences, also illustrates this concept of *emergence* (see Fig. 3).

Figure 3 Consilience: The vertical integration of the sciences, or the unity of knowledge.

Emergence

Once stars and planets exist (physical and chemical artifacts in the domain of Astronomy), and also Physics, Chemistry, and Geology (including their systems-laws governing water, land, and an atmosphere on a stable planet), single-celled and multi-cellular life (organic chemistry) and a biosphere may emerge over deep time, as it did on Earth 3.5 billion years ago. In individual self-replicating lifeforms an Evolutionary Psychology emerges aimed at survival and reproduction, namely “IF/THEN/ELSE” decision-algorithms such as instincts, behaviors, cognition, and a spectrum of consciousness. Groups of social lifeforms enable Social Systems (thus an Evolutionary Sociology) to emerge. Societies develop Evolutionary Cultures, a set of problem-solutions that are either selectively retained as canon, or discarded as archive. The canonical units (memes) are transmitted “horizontally” to others socially, and also “vertically” across generational lifespans via communication media (recorded language, writing, books, films, and so on).

In physical terms, an evolutionary algorithm (Variation, Selection, Transmission) operates on the units within each domain, and also on the cultural knowledge about each domain, via “Domain, Person, Field, interaction” (DPFi) systems (Csikszentmihalyi, 1988, 2014), while in the newly-emergent “Creativity 4.0” (Csikszentmihalyi and Gruner, 2018), Artificial Intelligence also enters into the DPFi systems model. On micro levels, the peer review of academic journal articles for a domain in culture is one example of a DPFi system, with peer reviewers and editors acting as “gatekeepers” to the canon of that journal. The emergent domain of the scientific study of units of culture (memes: ideas, processes, products) is Evolutionary Culturology. In Fig. 3, Mathematics underpins all these domains due to the striking efficacy of mathematics and complex systems theory in the natural sciences (Wigner, 1960; von Bertalanffy 1968), and also due to the high probability that we are living in a simulation of a multiverse (see Bostrom, 2003).

Using these conceptual tools of holon/partons and Systems Thinking, we now turn to the units of culture.

The Holon/Parton Structure of the Meme, the Unit of Culture

Velikovsky’s Ph.D. appendix (2016b) included the following model. This discovery allows for scientific analysis and comparison of the discrete units, levels, mechanisms and processes of selection in culture via methods in Applied Evolutionary Epistemology, the Digital Humanities, and related disciplines. A diagrammatic analogue of holon/partons appears in Fig. 4.

Holon/partons are fractal (self-similar in structure) when viewed on different scales. An analysis of some written text—as holon/partons—appears in Fig. 5.

Just as quarks-to-multiverses can be seen as holon/partons governed by three laws of physics, units of culture are also governed by these same three laws of holon/partons. The units and levels of “external” culture (or “e-memes”) can be distinguished, centering on a unit (a book) in the cultural domain of canonical books (see Fig. 6), be it a novel or a nonfiction book (e.g., *Don Quixote*, *To The Lighthouse*, *On the Origin of Species*, *The Selfish Gene*, and so on).

Each of these units of culture—on each level (in Fig. 6)—are holon/partons. Each unit obeys the same three laws: they (1) compete, and/or co-operate “sideways” with other units on the same level; (2) control and command “downwards” the units on the level below; and (3) integrate “upwards” into the larger unit above. This is to note that any canonical book competes for human attention with other extant canonical books within its literary genre; with all other canonical books in a culture; and with all other communication media in culture (e.g., television, films, games, the internet, electronic social media and so on). Moreover in composing a book, a writer must select a single word at a time from among all its competing synonyms. On levels “above” the word, authors also rewrite sentences from competing alternative sentence structures (oftentimes under an editor’s direction, using selective retention). While a unifying concept (or idea) underpins any single book, the additional laws (codes, rules) that determine each unit also change, as the levels change. Namely, the laws governing sentence structure (see Pinker, 2014) differ from the laws, rules or codes determining a (coherent, canonical) book’s chapter organization; and those are not the same rules as those governing a literary canon, or a genre, or library corpus selection. Yet all the component units, on all levels, behave as holon/partons according to the three laws of physics. E. O. Wilson (1998, p. 291) suggested that laws of physics might apply to culture, and on this view it indeed appears to be the case.

Figure 4 A Cantor Set, showing the structure of a holon/parton. Single units on each level are shown on the right.

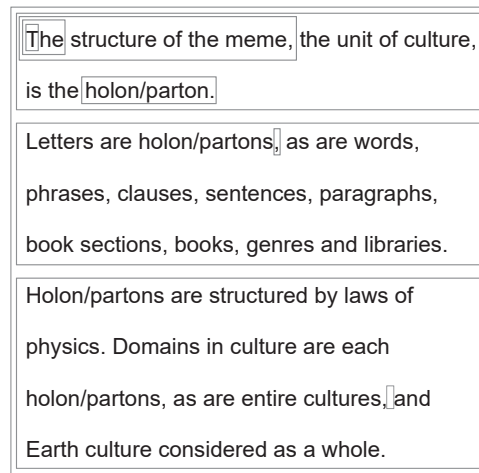

Figure 5 The holon/parton structure of units of culture applied to some written text. Adapted from Velikovsky, J.T., 2016a. The holon/parton theory of the unit of culture (or the meme, and narreme) in science, media, entertainment and the arts. In: Connor, A., Marks, S. (Eds.), *Creative Technologies for Multidisciplinary Applications*, IGI Global, New York, p. 220.

Figure 6 Units of culture in a canonical book. Each unit on each level is a holon/parton.

Using the same holon/parton Systems View, the units and levels of selection in other domains (or “species”) of culture can be identified, including in movies, games, plays, songs, poems, jokes, spoken language, science, art, and religion (see Velikovsky, 2016a, 2017a, 2018a, 2019). The discovery of this scientific model—the holon/parton structure of the meme, the unit of culture—may apply universally across all canonical cultural domains, and can be tested in non-English languages and cultures (even in the atypical Pirahã culture) with the aim of Popperian falsification.

E-Memes and I-Memes

The information stored in this encyclopedia is an external unit of culture (an e-meme) until a reader internalizes it, by perceiving and comprehending it; it then becomes an internal unit of culture (an “i-meme”), stored in their short-term memory.

External units of culture (e-memes) are ideas, processes and products manifested outside the human mind as physical cultural artifacts in the world (Popper’s “World One”). Examples include ideas—or algorithms (processes)—that have been written down or otherwise recorded (a cooking recipe, scientific theory or method, computer program, architectural blueprint, movie screenplay, sheet music and lyrics, religious text); also construction tools (hammer, nail, saw, forklift, crane) and other human-made artifacts (vehicles, bridges, buildings). A song played on the radio, a movie exhibited in a cinema, and a verbal conversation are all e-memes. When humans absorb and remember a specific e-meme—or segments thereof—it becomes an i-meme in their minds (see Fig. 7).

Parts (or wholes) of e-memes in the external world can become i-memes in a mind, such as a catchy chorus from a song; a memorable line of dialogue from a person, famous historical figure, play, movie or television show (see “100 Best Movie Quotes” in *Relevant Websites*); a creative scientific theory (such as $E=mc^2$); or a joke; and may be transmitted in the infosphere (the “e-meme pool”) via word of mouth, written form, or any communication media. The well-adapted (i.e., creative or “favored”) problem-solutions in culture are transmitted among the field (the audience, or consumers in a domain) and become canon, while the less well-adapted (uncreative) ones recede in the frequency of their occurrence and become archive.

The organic environmental niches for i-memes are human minds; currently these number around 7.6 billion on Earth. The English language (or parts thereof) is an i-meme in approximately 1.5 billion of these human minds, and also exists as e-memes stored in physical dictionaries, in English language course materials, on the internet, and in other communication media. I-memes are thus *learned* units of culture (ideas, or processes, or products) stored in a person’s memory, inside a human brain or nervous system.

Figure 7 E-memes and I-memes, and their relationship to Popper’s “Three Worlds”. In Figure 7, the two overlapping (inner) circles represent an individual person’s awareness of specific e-memes, and of i-memes already stored in their memory. The two larger (outer) circles represent all external (e-meme) units of culture, and all internal (i-meme) units of culture that exist.

Measurement of Memes (as E-Memes and I-Memes)

Cognitive science currently measures the new units added to a human's short term memory as "chunks" (Miller, 1956) or as engrams, while external information (as e-memes) are usually measured in Shannon and Weaver's (1949) "bits" (binary digits) and bytes. The size of the newly-stored chunk or engram for an i-meme in each individual human instance depends on many variables including: (a) what the person already knows; (b) Bayesian learning (updating one's worldview based on new data); and (c) Kullback-Leibler divergence (a mathematical measure of surprise). As functional Magnetic Resonance Imaging (fMRI) technology improves, individual i-memes (mental representations of ideas, processes, products) will be more accurately scientifically measured and compared in each case to the equivalent e-meme size (in bytes). Remembering a new word and its meaning is one thing, remembering the precise font, font size, and color that it was written in when perceived also depends on the subject's prior knowledge and awareness of those subdomains in culture, their multiple intelligences (Gardner, 2011), and where they lie on the Sensory Processing Sensitivity (SPS) spectrum, among other variables.

Some Mechanisms and Laws of Cultural Evolution

In biological evolution, the operation of the (macro) evolutionary algorithm on genes is generally viewed as such: variation (mutation of genes), selection (natural, sexual, artificial, or unconscious) operating on the organism in its environment; and heredity (the inheritance of the selected genes by the offspring) (Dennett, 1995).

However there is another (micro) view of the same algorithm, as specifically used in evolutionary computation and Artificial Intelligence. This is the iterative, recursive, evolutionary algorithm of: (1) *selection* (of one or more units from a pool); (2) *variation* (via combination of elements of units; variation can also occur due to mutation and copying errors); and (3) *transmission* (of the new unit) back into the pool, where natural selection (by the environment—including predators, a struggle for survival, selection pressures, fitness landscapes, and falsification) can delete the less-adapted units. This selection-variation-transmission (SVT) systems process operates on a micro level in both biological and cultural ecosystems (see Fig. 8).

In creativity, this "combination of elements" process is Koestler's (1964) "bisociation"; or Fauconnier and Turner's (2002) "conceptual blending"; or Brandt and Eagleman's (2017) "bending, breaking, or blending" process.

In biology, two organisms may select each other (via sexual selection) and blend parts of themselves via DNA to form a new unit (their offspring) and later release that new unit back into "the wild" (the pool), where natural selection may well delete (or archive) it, before it can repeat the algorithm—namely copy 50% of itself via sexual reproduction, and raise its own offspring to reproductive maturity.

In (bio)culture, artists, writers and scientists can *select* i-memes (ideas, processes, products) from their memory, then *vary* or mutate them (via: combination of elements, in their imagination) and *transmit* the new resulting unit back into the e-meme pool, where the field (audience or consumers) can judge it via natural, artificial, or unconscious selection. The new e-meme unit

Figure 8 The SVT Evolutionary Algorithm: Selection, Variation, Transmission.

thus becomes either canon or archive in a domain in culture, and this iterative, recursive, algorithmic cycle continues in more human minds. As Colin Martindale expressed it:

“Ultimately, all creative products have this quality: old ideas or elements are combined in new ways. This is the case for all domains of creativity”.
(Martindale, 1989, p. 212)

Emerging from The Newcastle School of Creativity (see McIntyre et al. 2018), Velikovsky's (2016a) model of cultural evolution synthesizes aspects of Csikszentmihalyi's sociocultural systems model of creativity, Simonton's BVSR model of creativity, Bourdieu's practice theory and Sawyer's (2012, p. 218) nested audiences model. The resulting Creative Practice Theory evolutionary systems model of creativity that underpins this view of the holon/parton structure of the meme, the unit of culture, appears in Fig. 9.

In this (macro-scale) Domain, Person, Field bio-psycho-socio-cultural interaction model: The *Person-system* contains a (micro-scale) Memory, Imagination, Judgment interaction (or MIJi) system within their mind, and uses an evolutionary process of Blind Variation (via imagination, or “mental simulation”) and Selective Retention (judgment, and memory) to generate viable new memes–(and discard unlikely ones)–as i-memes, which they can then present (transmit) to the field as e-memes (tangible cultural artifacts). The Field then judges these e-memes (ideas, processes, products). Around 1% of these e-memes either go into the domain's canon (e-memes judged as creative; new and useful) and the other 99% go into archive (e-memes judged not creative, and which are ignored or forgotten by the Field, and thus rarely reappear as e-memes). The canon for a specific domain in culture thus changes over time as better solutions and additional new problems emerge.

Multi-level selection in evolutionary algorithms operating on units in biology (genes, DNA, cells, organisms, groups, superorganisms, species) and also on memes in culture (ideas, processes, products; or culture at various levels of the holon/parton) thus results in biological and cultural survival and extinction; growth and decay; creative and uncreative artifacts; or more simply, canon and archive.

In a statistical sense, biology and culture are similar in that 99% of Earth's biological species have gone extinct over time, due to evolutionary algorithms and multi-level selection operating in the ecosystems of a changing Earth environment, and likewise, around 99% of cultural artifacts are deselected (rejected) by the Field and become archive.

“Viral” Memes a.k.a. Creative Units of Culture

A “viral” meme is simply a term for what many scientists, artists, engineers, inventors and cultural practitioners aim to create, namely a creative unit of culture—or in other words, an idea, process or product whose time has come according to the consensual judgment of the field. How widely the new unit spreads in a domain as an e-meme—and thus in the minds of the field as an i-meme—ultimately determines where exactly on the 5-C spectrum of creativity (Fig. 10) the meme resides in the judgment of the current field.

Fig. 10 is a synthesis of The Four-C Model of creativity (Kaufman and Beghetto, 2009, 2013), and the fifth category of “boldface-C Creativity” (Simonton, 2010, p.175). Instances of Everyday creativity occur frequently as people solve their everyday problems in new and useful ways, but the wider field for that domain (everyday people in everyday life) is rarely aware of these. Meanwhile on the 5-C spectrum of creative memes (Fig. 10), selling a million units of a book, movie, song or videogame (“pro-c” creativity) is considered impactful, and Eminent Genius level (boldface big-C) Creativity is legendary creativity (e.g., Einstein, Picasso, Mozart, Kubrick, Austen). Darwin's theory of evolution (in both biology and in culture) is thus a “category 5” meme (boldface big-C Creativity); as are Newton's and Einstein's theories of gravitation; Da Vinci's *Mona Lisa*; The Beatles' *Sergeant Pepper's Lonely Hearts Club Band*, Michael Jackson's *Thriller* and Led Zeppelin's *IV* albums; Beethoven's *fifth Symphony*; many of Shakespeare's phrases. Category 5 memes have obvious spreading power as problem-solutions. These are re-communicated in culture—in part, or as wholes—depending on the size of their memorable “chunks” in Miller's (i-meme) terms, or bytes in (e-meme) Shannon information. On this view, the Abrahamic religions of Judaism, Christianity, and Islam are also category 5 creativity, given they exist as i-memes in around 53% of the world's 7.6 billion human minds. Conversely there are over 4000 recorded deities in culture, many of which are now archive as i-memes (See “Godchecker” in Relevant Websites).

Stories (Narremes) as Memes

Stories (narratives) are also units of culture. Memes (of both the i-meme and e-meme type) include “narremes”, or *units of story*, which—being memes—are also structured as holon/partons. Gottschall (2012) noted that a narrative is an algorithm, of the formula: *Story = Character(s) + Problem(s) + Attempted Solution(s)*. One popular story algorithm is the “monomyth” or hero's journey (Campbell, 1949), which can be seen as an algorithm for creative problem solving on a macro scale, for example when applied to the life work of biologist/writer Charles Darwin and the filmmaker/writer Stanley Kubrick, and on a micro scale when applied to their individual creative projects (Velikovsky, 2018b). Velikovsky's Ph.D. study (2016b) examined 40 units of culture, comparing traits of the top 20 Return-on-Investment (most profitable) movies (as canon) to the bottom 20 Return-on-Investment (biggest money-losing) movies (as archive). The memes on all unitary levels in a movie (including its narremes—as memes) can be counted and measured, including individual dialogue lines, words and phonemes spoken by actors, words sung on a soundtrack, and so on. Movies are

Figure 9 DPFi and MIJi systems, and Seven Categories of Canon (and one of Archive) in a Domain. Adapted and synthesized from Velikovsky, J.T., 2017b. Introducing 'The Robo-Raconteur' artificial writer - or: can a computer demonstrate creativity? *Int. J. Art Cult. Des. Technol.*, 6, 42-3 and Velikovsky, J.T., 2016a. The holon/parton theory of the unit of culture (or the meme, and narreme) in science, media, entertainment and the arts. In: Connor, A., Marks, S. (Eds.), *Creative Technologies for Multidisciplinary Applications*, IGI Global, New York, p. 228.

Figure 10 The 5-C spectrum of creativity. Adapted from Velikovsky, J.T., 2018b. Darwin & Kubrick, Joe Campbell & Me: eminent-genius and everyday-joe heroes on a journey. J. Genius Eminence 2, p. 63.

information-rich cultural artifacts, as while a movie screenplay or a novella (as an e-meme) typically contains around 150 kilobytes of Shannon information, the average (90-min) movie is an e-meme of around three gigabytes when digitally compressed as a DVD, and around 250 gigabytes as an uncompressed e-meme (as a movie experienced in a cinema).

Growth of a Unit of Culture

Just as evolution in biology tends to unify “upwards” and to diversify “downwards”, so too inanimate units in culture can, in the broad sense, “grow”. A transmedia story universe, also sequels in the same media, or adaptations of a story universe to other media (such as book-to-film) can result when a unit of culture “expands” in this way. A transmedia universe (such as the *Harry Potter*, *Star Wars*, *DC* or *Marvel* comics universes, also religions, and the scientific history of a domain) grows in this manner as new cultural units are added to it (see Fig. 11).

Figure 11 A transmedia fictional story universe, unifying upwards while diversifying downwards, as new units emerge (a novel, movie, game, etc.) and thus new characters, settings, events and themes are added to the whole story universe as a single overarching meme, or unit of culture.

The Creative Practice Theory Model of Cultural Evolution

The model of Creative Practice Theory (Fig. 12) is a Venn diagram, symbolizing that if all of the elements in each set are present (the Domain, Person, Field system; and, Economic, Social, and Cultural Capital), having produced a creative artifact, a creative person may also ultimately obtain Symbolic Capital.

Over time, as more problem-solutions emerge, culture speciates off into discrete, differentiated Domains (see Fig. 13) as technology evolves.

Evolutionary History (Harari, 2015) shows that language led to writing and books; the domestication of fire has led to cooking and the culinary arts; the invention of the wheel led to motorized transportation and electric cars; powered flight has led to aircraft, and so on. As technology complexifies and diversifies (downwards) in Fig. 13, all of these domains also unify (upwards) as elements of human (Earth) culture. We can examine such evolution of culture in broad terms, and track when different disciplines (scholarly academic fields for specific domains) have emerged over time due to advances in technology (see Fig. 14).

Fig. 14 indicates when the first international conference for various domains was held; namely the official origin of a discrete global field of experts for that domain of knowledge in culture. As domains of knowledge fall out of Philosophy, they unify “upwards” into Science and they simultaneously speciate “downwards” into subdomains. For example Evolutionary Biology now includes the subdomains Physiology and Anatomy, Ecology, Neurophysiology, Archeology, Paleontology, Genetics, Epigenetics and more. Conversely, pseudo-sciences such as astrology, psychoanalysis, parapsychology and phrenology have all been archived in the sciences.

Languages and Cultural Evolution

In languages, certain graphemes in English such as “æ” can also be observed going extinct over time. An examination of two alternate spellings of encyclopedia (encyclopaedia, and encyclopædia) via a Google NGram (Fig. 15) demonstrates a three-way battle

Figure 12 Creative Practice Theory, 2-D model (Velikovskiy, 2016b, p. 61). See the *Glossary* for definitions of Economic, Social, and Cultural Capital, and habitus. An animated 2-D model shows this 12-stage CPT process, over time (see *Relevant Websites*: “Creative Practice Theory”). See also: Sawyer’s “Eight Stages of the Creative Process, and how they correspond to other process models” (Sawyer, 2012, p. 89).

Figure 13 A tree of technology: Unification upwards and complexification downwards in culture.

for survival from 1720 to 1820 and the archiving of “encyclopædia” as the other spellings fill that cultural niche as a problem-solution.

An NGram graph—as a guide to e-meme frequency—can serve as a proxy for the i-memes in circulation during that era.

Summary of Some Mechanisms and Laws in Cultural Evolution

Some of the key mechanism of cultural evolution include: the (micro) evolutionary algorithm of selection, variation, and transmission of i-memes by persons; also the (macro) selection of e-memes as canon by the field for a domain. Some laws in cultural evolution include: the three laws of holon/partons in cultural canon; selection pressure; and unification “upwards” and simultaneous complexification (and speciation) “downwards” in culture as units “grow”.

Memes can be defined rigorously (as: ideas, processes, products) and also mathematized, including via agent-based models and artificial intelligence computer programs. Once i-memes (ideas in Popper’s “World Three”) are expressed as e-memes (in “World One”) they become tangible, concrete, and measurable units. Units of culture (memes) themselves are not able to suffer; do not have anthropomorphic goals, desires, or intentions (a.k.a. problems), but rather, problems (goals) are possessed by the users of technology (humans or other animals). Converting an idea, process or product from a mental i-meme into a physical e-meme is a process of expressing a meme in a physical substrate; the reverse process (perceiving and absorbing an e-meme, thus converting it to an i-meme) is abstracting information from its concrete physical substrate. Certain memes (ideas, processes, products) can also exploit niches in peoples’ worldviews via cognitive biases. If a meme (and its resulting behavioral effects) reduces psychological stress or anxiety, it may not matter to the user if it is true (including chain letters, conspiracy theories, religious or political beliefs).

Creativity as By-Product of the Evolutionary Algorithm

In either biology or in culture, when units exist in a pool inside an ecosystem and compete for finite resources (such as food, shelter, and mates in biology; or human attention and dominance in culture)—and units are selected, varied (combined) and transmitted back into the pool—some will be better-adapted to that environment than others. Selection pressure separates these units into *canon* (new and useful; novel and appropriate; original and adaptive; unique and effective) and conversely, *archive* (uncreative). On this view, creativity is an inevitable byproduct of the evolutionary algorithm operating in ecosystems. The genes—and the memes—that

Figure 14 A Tree of Culture: A timeline of the emergence of international fields for domains. (Timeline is not to scale, but is compressed for reasons of clarity.)

Figure 15 A Google NGram of the words “encyclopedia”, “encyclopaedia”, and “encyclopædia”.

are extant (or canon) rather than extinct (or archive) are the most creative ones, as judged by the environment. In broadest view, humans construct bio-cultural (technological) niches via creativity, using memes as problem-solving tools.

Biology Contains Culture

Organisms are systems with algorithms (processors) inside them. If culture is viewed as *information*, then biology contained internal culture (i-memes) when Life first emerged—three billion years before *Homo Sapiens* appeared—let alone before humans invented external culture (e-memes) such as language, domesticated fire, the hand-axe, the wheel, writing or the internet. A new formal definition of information was proposed by Colgate and Ziock (2011) which incorporates this view, and sees culture as symbiotic rather than parasitic in biology. Some i-memes may be viewed as mental parasites, or a “mind virus”. However in each specific case, we can examine the benefit/cost ratio of the e-meme and i-meme (the idea, philosophy, worldview; process; or product) to determine its overall value to life and society in terms of its behavioral effects, and bio-psycho-socio-cultural as well as ecological impacts.

New and Useful Solutions to Grand Challenges in Cultural Evolution

In 2017 the founders of the Cultural Evolution Society published an article on the eight current major “Grand challenges for the study of cultural evolution” in *Nature* (Brewer et al., 2017). The holon/parton structure of the meme model of culture impacts these challenges, shedding light on some prior mysteries.

Conclusion

A meme, a unit of culture, is a problem-solution in the form of an idea, process or product. Some memes exist as two or all three of these categories (the *idea* of a journey; all the *processes* involved in a journey; the physical journey in space-time involving many e-memes (*products*, such as photographs); and the i-meme memory of the completed journey).

Units of culture (memes) exist because all creativity, like all life, is problem-solving. Problems (goals) emerge with life, and also from human goals (or problems) such as those on Maslow’s hierarchy of needs.

The unit of culture can be viewed as the holon/parton, in all canonical domains in culture. These units can be counted, tracked and measured with some accuracy with regard to e-memes (external units) using Big Data research tools from the Digital Humanities (Google NGrams, citation counts, unit sales, library holdings, and so on) whereas i-memes (as individual human mental information) are much harder to accurately track given how much—and how fast—information constantly circulates in global human minds.

New units of culture emerge from evolving bio-psycho-socio-cultural-economic systems as an inevitable byproduct of the evolutionary algorithms operating on biology, and on culture. The creative units (around 1%) become cultural canon, while vastly more (around 99%) become archive. As problem-solutions, units of culture (memes) can impose some order on the chaos of the universe, in spite of the three laws of thermodynamics.

Introduction

From ancient poets and architects to modern scientists and engineers, creativity is the fuel for societal and technological development. Accordingly, understanding creative individuals, events, processes and outcomes has been a major topic of scientific inquiry, with scholarly investigations spanning an array of fields from psychology, education, sociology to management (Amabile, 1996; Amabile and Kramer, 2011; Runco, 2015; Runco and Acar, 2012). Yet, while most scholars from different disciplines have come to a common understanding of creativity as the production of novel and useful ideas (Amabile, 1983), the focuses and approaches to examining creative individuals and processes vary to a large extent (Ellamil et al., 2012; Gino and Ariely, 2012; Zhang et al., 2019; Zhang et al., 2015). Researchers in cognitive and neuroscience, for instance, view creativity as resulting from activation of certain brain regions (e.g., Zabelina and Robinson, 2010; Dietrich, 2007; Dietrich and Haider, 2017), whereas studies in the fields of management and applied psychology deem creativity as a product of organizational systems and social interactions (e.g., Hargadon and Bechky, 2006; Nijstad and De Dreu, 2012; Zhou et al., 2008; Zhou and George, 2001).

The myriad of foci and topics around creativity makes it necessary to clarify the spatial structure of the creativity as a research field, as well as similarities, differences, and interrelations among different research paradigms. Employing social network and co-word analysis, Zhang et al. (2015) have recently shown a knowledge map that summarizes 4575 published articles in the broad domain of creativity from 1992 to 2011. In particular, the authors adopted K-core of social network analysis and co-word analysis to draw the key words network and the spatial structure of research topics and paradigms in creativity. They inferred five main topics: creativity applications, pathology & physiology of creativity, individual creativity, organizational creativity, and theories and methodologies. In addition, there have been other maps of the creativity research (e.g., Williams et al., 2016).

Such a knowledge map, on top of discovering the current state of research, allows us to better understand research hotspots and recognize further opportunities. This chapter attempts to update Zhang et al. (2015) by including a larger, more recent sample of articles published between 1999 and 2018. Given that creativity research abounds in the past few years, such an update may result in a somewhat different map, extending our understanding of major topics and their interconnections across fields. In the subsequent sections, data source and collection procedure will be explained, followed by data analysis. Major findings will be discussed and compared to Zhang et al. (2015). The chapter will conclude with implications for future research avenues.

Data Source

The publication data in creativity research were extracted from the core collection database in the Web of Science, which contains more than 12,000 peer-reviewed academic journals covering natural sciences, engineering, biomedicine, social sciences, arts and humanities. The earliest data date back to 1900. The core collection of Web of Science includes references cited in a paper and a unique citation index based on cited author, affiliation, title, keywords, abstract, the number of citations, source, and publication year. This database includes eight sub-libraries: Science Citation Index Expanded (SCI-EXPANDED), Social Sciences Citation Index (SSCI), Arts & Humanities Citation Index (A&HCI), Conference Proceedings Citation Index-Science (CPCI-S), Conference Proceedings Citation Index-Social Science & Humanities (CPCI-SSH), Emerging Sources Citation Index (ESCI), Current Chemical Reactions

(CCR-EXPANDED), and Index Chemicus (IC). Based on our research purpose, three related core sub-libraries—SCI-EXPANDED, SSCI, and A&HCI—were selected as the final sources of data.

As the abstract provides a summary of the content of the document in a concise and precise manner, it includes the aim and scope of the research, the methods used, the results and main conclusions, which is an independent, self-evident, and abbreviated form. Thus, while we did not read the original text verbatim for every article, we were able to grasp its essential information from the abstract.

In order to reveal the paradigm structure and knowledge mapping of creativity research, the publication data were retrieved from the cited papers whose abstracts contain “creativity”. Specifically, as representing the “abstract” in the Web of Science database, “topic” was selected as the search condition and “creativity” was entered as the query content. Meanwhile, the time span was set to 20 years (1999–2018), matching that of Zhang et al. (2015). This procedure resulted in 19,084 papers extracted that contain “creativity” in their abstracts. Further, “noise” papers whose document types are book review (1106), editorial material (960), review (746), proceedings (634), meeting abstract (454), letter (107), book chapter (93), news item (44), biographical item (35), or correction (33) were deleted. The number of papers retained with the “article” document type is 15,571. Thirdly, the citation rate of a paper illustrates its contribution to filed research. If the paper has never been cited by others, it will not be included in our research data for analyzing paradigm structure and knowledge map. Since the papers published in 2018 were very recent, and it takes some time for citations to appear for an article, the papers which was not cited by others in 1999–2017 were deleted, which further reduced the number of papers to 12,926. Finally, the co-word analysis requires at least two keywords per article. Therefore, papers with no keywords (1,012) or only one keyword (310) were deleted, which yielded the final sample of 11,604 papers to be analyzed. The annual published papers included in the final analysis are shown in Fig. 1, which indicates that the number of papers published in the field of creativity has increased year by year in the past 20 years.

Methodology

Originally developed by sociologist Harrison White in 1960s and extended by his successors by combining mathematical analysis with graph theory, social network (SN) represents a set of actors as well as their relationships. The actors and relationships, as visualized by nodes and ties in social network programs (e.g., UCINET), then serve as data source for various analyses. Recognizing its analytical power, scholars in information science have recently adopted SN analysis to examine research collaboration and citation networks (Otte and Rousseau, 2002). To date SN method has proved a powerful tool in understanding “small worlds” of scientific communities (Newman, 2001) and self-organizing nature of international co-authorships (Wagner and Leydesdorff, 2005). It can also reveal the network of keywords in published articles in a given research domain. As it is critical to understand internal structure of a SN (Scott and Carrington, 2011), the method of K-core, with its advantages in citation analysis, paradigm identification, and knowledge map building (Wasserman, 1994), was used to uncover how subgroups make up the whole keyword network.

Second, the basic tenet of co-word analysis is that keywords in a single paper represent the main subject areas of that paper (Ding et al., 2001). As a content analysis method to assess theme ties in a specific topic area, co-word analysis can display its research structure based on keyword frequency. By extracting keywords or theme words from the literature and retaining those of high frequency using a set threshold, it was able to count the frequency that each pair of keywords simultaneously appears in the literature, and form the co-word matrix, which helps us understand hot topics and structure of co-keywords or co-theme words (Ding et al., 2001). Following previous bibliographical research in different disciplines (see Zhang et al., 2015 for a review), co-word

Figure 1 The annual number of publications included in the data.

analysis was employed to map the research structure of the creativity field, which then reveals associations of keywords as well as paradigms and sub-communities.

Furthermore, to illustrate the extent topics and academic communities are connected to or separate from one another, a distance-based measure—multi-dimensional scaling (MDS) was adopted—to classify samples or variables with many dimensions by similarity (distance). Specifically, MDS will generate a map of objects denoted by points, with similar objects (points) gathering together to form a category. The level of centrality of a point in the network shows the importance of the point (object). Following [Zhang et al. \(2015\)](#), Non-metric MDS was employed, as it allows analyses of ordinal scale data.

Fourth, visual analysis is a recent development in information technology. It can process and visualize abstract data, clarify and transform complex and fuzzy data, and uncover hidden information in the data. Such a technique integrates research theories with various methods from fields such as graphics, data mining, human-computer interaction, cognitive science, and image technology. CiteSpace program was used to visualize data and develop knowledge map. CiteSpace can find authors, journals, quoted words, and keywords in the literature, explore their connections, and eventually identify trends in the topic area.

Data Description

Data collected for the study contain a total of 26,557 authors and 11,604 papers between 1999 and 2018, with an average of 2.29 authors per paper. Among them, the top 25 authors who published their papers on creativity are listed in [Table 1](#). For instance, Kaufman of the University of Connecticut ranked first, with 73 publications on creativity. Fink and Benedek, both from Karl Franzens University Graz, ranked second and third respectively, followed by Mumford (University of Oklahoma), Silvia (University of North Carolina Greensboro), and Simonton (University of California Davis), all of whom had published more than 40 articles. Karwowski of Maria Grzegorzewska University, Qiu of Southwest University in China, Runco of University of Georgia, De Dreu of Leiden University, Nijstad of University of Groningen, and Lubart of University of Paris ranked seventh to 10th. Of eleven authors in the top ten, five were from the United States, five from Europe (two from Austria, two from the Netherlands, and one from France), and one from China.

In addition, the 11,604 papers involve 6,918 universities or research institutes, representing a rather broad base. The top 25 institutions that published creativity papers are shown in [Table 2](#). Among them two were from the Netherlands, three from the United Kingdom, one from Canada, two from China, one from Australia, and the remaining 16 were all from the United States. It is apparent that most creativity research were conducted by scholars from research institutions in the North America and Europe. Interestingly, two Chinese universities, one from Hong Kong and the other from Taiwan, are also among the top 25, which demonstrates that universities and institutions outside the United States and Europe have also developed research capability in the field ([Table 3](#)).

and Chinese region had published about three fourths of articles around creativity, representing three major countries/regions. Additionally, besides developed countries/regions, emerging economies such as Russia and Brazil were also on the list.

Table 4 lists the top 25 articles by citation count, which is generally regarded as a measure of scholarly impact and contribution. **Burt's (2004)** paper on structural holes and creativity (published in *American Journal of Sociology*) ranked first, with a total of 1637 citations. **Peck's (2005)** work on analysis of the reception and ramifications of creativity policies in the city of Amsterdam (published in *International Journal of Urban and Regional Research*) received second most citations (966). The third most cited article (739) was **Zhou and George (2001)**, who theorized that useful feedback from coworkers, coworker helping and support, and perceived organizational support for creativity should each interact with job dissatisfaction and continuance commitment to result in creativity (published in *Academy of Management Journal*). **Deci and Ryan's (2008)** paper (published in *Canadian Psychology*), ranked fifth with 700 citations, links creativity to motivation. Overall, the top 25 articles cover a wide range of disciplines including sociology, psychology, management, public administration, economic geography, health care, etc. Among the 25 articles 13 were published in *Academy of Management Journal*, *Journal of Applied Psychology*, or *Leadership Quarterly*, all of which belong to the broad management domain, indicating a burgeoning area of research among management scholars in the last twenty years.

The preceding tables and descriptions summarize top authors, institutions, countries/regions, and articles by citation count. To help creativity scholars better understand potential journal outlets for papers around creativity, the number of publications by journal and listed top 25 journals that published creativity papers was counted. As shown in **Table 5**, *Creativity Research Journal* had published 543 articles, significantly outnumbering all the rest. *Thinking Skills and Creativity* and *Journal of Creative Behavior* ranked second and third, together with a total of 540 publications. The journals that contributed to most publications range from domains of psychology and management, to those of design and education.

Data Analysis

Author Co-occurrence Analysis

To understand the pattern of research collaboration, author co-occurrence analysis was conducted. **Fig. 2** illustrates authors' social network, which reveal diverse and distributed collaboration relationships. For instance, as shown in the network, there were multiple subgroups of collaborators represented by one or two major scholars. The subgroups were either fairly independent (e.g., the Mumford, Runco, and Simonton subgroups), or clustered together (e.g., the Benedek, Fink, and Neubauer subgroups). Interestingly, the largest cluster was formed by several subgroups led by Kaufman, Karwowski, Silvia, and Beaty). With both heterogeneity and centralization, such a network structure ensured content diversity and knowledge integration, which was beneficial for creativity research to develop as a multi-disciplinary field.

Affiliations Co-occurrence Analysis

Fig. 3 demonstrates authors' affiliation co-occurrence network. At the center were major collaborating universities such as Pennsylvania State University, University of Pennsylvania, Georgia Institute of Technology, University of Connecticut at Storrs, Maryland University and University of Illinois. Based in the US, these universities connected and bridged other universities and research centers in different countries/regions. Albeit ranked first, Harvard was not at the center of the network; rather it grouped with University of Toronto and Graz University on the upper-left corner. The lower-right corner presents a local network including a few UK universities such as Nottingham, Oxford, and University College London. Two Dutch universities—University of Groningen and University of Amsterdam—formed another small collaboration network on the right side of the figure. Finally, some universities from Hong Kong and Taiwan were well connected with universities in California (e.g., Stanford, UC Berkeley, UC Davis).

Countries or Regions Co-occurrence Analysis

University network reflects collaborative research outputs by institutions, whereas countries or regions' collaborative network stand for breath of collaborations across national or regional borders. As shown in **Fig. 4**, in a marked contrast to authors' network, national/regional collaborative network had a rather dense structure, indicating close connections and joint work among creativity scholars around the globe. The US, Canada and Netherlands were located in the center of the network, representing the largest subgroup. Another two major subgroups were led by UK and Germany, which were, respectively, clustered by other European countries. Noteworthy is the subgroup composed of Asian Pacific countries such as The People's Republic of China, Taiwan, Japan, South Korea, Russia and Australia.

Keywords Co-occurrence Analysis

Using Citespace to process the full record data of 11,604 papers, it was able to obtain 30,243 keywords, based on which a keyword network was formed (**Fig. 5**). The figure reveals that keywords were well connected into an integrative network. Although Citespace is good for visualization of social network, it is limited in in-depth analysis of co-word occurrence. It thus relied on Bibexcel for the co-word analysis. After importing the full data in Bibexcel, 230 keywords with a frequency greater than 60 were retained. Integrating keywords with the same or similar meaning and combining the singular and plural forms resulted in 216 keywords, which were

used to construct the co-word matrix (Table 6). As shown in the table, “creativity” had the greatest frequency of 5504 times, followed by “performance” (1686), “innovation” (1400) and “model” (1054), all more than 1000 times. In addition, other keywords such as “personality”, “work”, “organization”, “employee creativity”, “divergent thinking”, “perspective”, “behavior”, “knowledge” and “intelligent” had frequency counts of more than 500 times.

With the 216 top keywords (shown in Table 6), Bibexcel was used to establish keywords co-occurrence matrix M , where $M \in R_{216 \times 216}$, partly shown in Table 7. Co-occurrence matrix M contains numbers representing the frequency that each pair of keywords appears in the same article. For instance, 310 shown in the cell located in the third column and the fourth row in Table 7, indicates that the keywords of “creativity” and “divergent thinking” simultaneously appeared in the same documents for 310 times. It should be noted that the numbers on the diagonal of the matrix are all zero, meaning that the same keyword cannot appear in the same article with itself. Next, we applied UCINET 6.0 to conduct the K-core analysis for keywords co-occurrence matrix M , in attempt to reveal the subgroups based on keywords’ network positions. Results show that 216 keywords were divided into 18 subgroups, whose node degrees were, respectively, 54, 53, 52, 51, 50, 49, 48, 46, 44, 42, 41, 40, 39, 38, 37, 35, 33 and 22. The node degrees of 84.3% keywords were above 50, which suggest that most of topics had been simultaneously examined by creativity scholars, and the topics had strong correlations. Furthermore, MDS was employed to observe the spatial positions of the 216 keywords in the keyword network, in hope of finding topic-based classifications and evolutionary paradigms. The keywords network and results of K-core and MDS was visualized by using the software NetDraw, which are shown in Fig. 6.

Discussion

Analyses of 11,604 published articles on creativity from 1999 to 2018 yielded results regarding authors, institutions, countries/regions, and keywords. Our discussion will center on the 216 high-frequency keywords (shown in the K-core and MDS map of Fig. 6), in attempt to uncover broad categories and spatial structure based on which to identify major creativity research domains and point to future research opportunities.

Six Categories of Research Topics

As shown in Fig. 6, the 216 top frequent keywords can be grouped into six broad categories of topics around creativity. At the center of the keyword network are keywords grouped in a purple circle. A close examination reveals that these keywords represent construct space of creativity, major theories on creativity, and methodological terms. In particular, definitions and dimensions of creativity are reflected in such keywords as “originality”, “flexibility”, “idea generation”, “value”, “validity”, “reliability”, “cognition”, and

Figure 2 Authors' cooperative network.

Figure 3 Authors' affiliation co-occurrence network.

Figure 4 National/regional collaborative network.

"creativity". Other keywords as "brainstorming", "networks", "communication", "collaboration", "integration", "individual-difference" represent key elements or processes of collective creativity. Further, another group of keywords stand for mainstream creativity theories, including some general theory-relevant keywords (e.g., "model", "system", "perspective", and "framework"), as well as specific theoretical approaches such as Amabile's (1983) componential theory of creativity (i.e., "expertise", "knowledge", "information", "divergent thinking", "thinking", "intelligence", "intrinsic motivation", "motivation"), the interactionist perspective stressing the interplay of individual characteristics and task context (i.e., "organization", "technology", "culture", "power", "strategy", "decision making", "time", "innovation", "task", "work", "self", and "behavior"), and their joint effects on performance ("impact", "success", "productivity", and "performance"). Finally, there are a few keywords denoting methodologies applied to the creativity research (e.g., "scale", "meta-analysis", and "validation").

Second, on the lower right side of the figure are 41 keywords (separated by a red circle) that tap into the cognitive and psychological aspects of creativity. Specifically, cognitive and neuroscience approaches to creativity are echoed in a number of words (e.g., "neuroscience", "brain", "language", "similarity", "analogy", "blind variation", "prefrontal cortex", "thought", "EEG", "representation", "activation", "schizophrenia", "schizotypy", "mental-illness", "psychopathology", "bipolar disorder", "memory", "working-memory", "cognitive control", etc.). Likewise, applied and social psychologists have studied creativity with such keywords as "positive affect", "hedonic tone", "self-regulation", "self-determination theory", "stress", "inhibition", "depression", "depression tests", "conceptual design", "creative thinking", "dual pathway", "Torrance tests", "consensual assessment technique", "engineering design", "social-psychology", "implicit theories", and "5-factor model". It is interesting that the keyword "Hong Kong" also falls into this category, probably indicating that a region-based interest in examining creativity from the cognitive-psychological perspective.

The third category, represented as the blue circle, covers topics related to the association of individual characteristics with individual-level creativity. More specifically, these keywords range from personality (e.g., "personality", "openness", "achievement", "psychology", and "trait"), emotion (e.g., "emotion" and "mood"), cognition (e.g., "attention", "perception", and "insight") to other individual-level variables such as "skills", "attitudes", and "gender difference". Together, these keywords demonstrate topic areas in which creativity research have been conducted at the micro level.

Conversely, the fourth category of keywords, a large group in the orange circle on the left side of the network, are mainly from creativity research in the organizational context. Further examination reveals a few sub-categories within this group. First, there are keywords that represent creative contexts, processes, and outcomes within organizations, be at the individual or team level. Examples include "group creativity", "teams", "contextual factors", "work-environment", "diversity", "goal orientation", "regulatory

Figure 5 Keywords network.

focus", "self-efficacy", "creative self-efficacy", "social identity", "participation", "identity", "identification", "engagement", "psychological safety", "psychological empowerment", "social network", "climate", "leader-member exchange", "transactional leadership", "transformational leadership", "leadership", "support", "conflict", "trust", "innovative behavior", and "organizational citizenship behavior".

Also in the fourth category, macro level (i.e., organization- or inter-organization level) creativity studies can be shown with such keywords as "firm", "knowledge management", "absorptive-capacity", "research and development", "product development", "exploration", "exploitation", "market orientation", "organization culture", "entrepreneurship", and "organization innovation". Further, there are other keywords dealing with methodological aspects of the studies (e.g., "moderating role" and "mediating role"). Finally, two country keywords—the US and China—also appear in this category, suggesting creativity as a major research area in the broad domain of organization studies in these two countries.

The fifth category, in the yellow circle, comprises keywords representing studies on policies and macroeconomic issues, within which three relevant research areas can be identified: economy and geography (e.g., "cities", "geography", "globalization", "economy", "industry", "growth", "creative industries", and "competitive advantage"), policies (e.g., "politics", "policy", and "government"), and society and environment (e.g., "dynamics", "communities", "context", "environment", "sustainability", and "ethics").

The last category contains keywords (in the green circle) that belong to basic disciplines of education, arts, science, and social science. Specifically, representative keywords include "pedagogy", "learning", "classroom", "children", "adolescents", "teachers", "play", "risk", and "assessment" for education; "aesthetics", "music", "art", "artists", "imagination", and "improvisation" for arts; "patterns", "science", "discovery", "evolution", "life", and "health" for science; and "history", "women", "people", "generation", "gender", and "age" for humanities and social science.

Table 6 Top 216 keywords (frequency ≥ 60).

Rank	Keywords	Frequency	Rank	Keywords	Frequency	Rank	Keywords	Frequency

Spatial Structure of Creativity Research

The K-core and MDS map in Fig. 6 embodies nodes' (i.e., keywords') relationships via the space and distance. Relevant indices such as density and centralization can be used to evaluate the network and discover sub-groups and their interconnections. The current study employed MDS technique to construct the knowledge map of keywords in creativity research, which provides the spatial structure in this research field. It also updates the knowledge map developed by Zhang et al. (2015). The similar findings were discovered in the two studies. However, the map by Zhang et al. presents five categories, that is, "creativity applications in different areas", "pathology and physiology of individual creativity", "individual-level creativity", "organizational-level creativity", and "basic theories and methodologies". Instead, the current study generated six categories, dividing the category "creativity applications in different areas" into two emerging categories—"policies and macroeconomic issues" and "basic disciplines of education, arts, science, and social science". Such a change suggests an increasing, refined attention to macro-level factors of industries and policies in recent creativity research, indicating a trend to apply well developed theories and frameworks to benefit production and societies. This is also consistent with the general pattern that mature sciences are more likely to be applied into practice.

The structure of the map shown in Fig. 6 features a central group with high density of network ties. The keywords connected through these ties concern core dimensions and definitions of creativity, essential creativity theories, and research methods applied in the area. In addition, the other surrounding groups, marked with different colored circles, contain keywords that represent studies exploring specific topic areas within the creativity domain. Some of these topics are highly specialized and may involve few scholarly conversation and collaboration across topic areas.

From right to left in Fig. 6, the keyword network starts with the group focusing on micro-level processes and mechanisms for individual creativity. For instance, neuroscientists attend to brain mechanisms that can produce creative thinking and ideas, while applied psychologists attempt to link creativity to individual personality, demographics, affect, attitudes, and so on. Further, it should be noted that studies on individual creativity had been conducted in a wide variety of disciplines, ranging from science, education, arts, to social science.

At the left side the group contains keywords that are extracted from articles examining team- and/or organization-level creativity. These studies explored creative processes and behaviors in the organizational context. Moreover, researchers in this line of research

Figure 6 The results of K-core and MDS on keywords network of creativity research. Note: Red diamonds, Orange circles, Blue Down Triangles, Gray boxes, Crimson Up Triangles, Yellow squares, Purple circles, Green squares, White squares, Things, Pluses, Dark blue diamonds, Circle-in-Box, Cyan Down Triangles, Green Boxes, Gray Up Triangles, Gray square and Gray circles respectively represent keywords with 54, 53, 52, 51, 50, 49, 48, 46, 44, 42, 41, 40, 39, 38, 37, 35, 34 and 33 node degree.

considered macro-level factors within and outside the organizations (e.g., social network, pro-creativity policies) related to creativity in a broad sense. Furthermore, at the bottom of the map is a long, flat circle composed of keywords representing studies that explore and extend theories on creativity. In contrast, the keywords concentrated in the top circle may come from research applying creativity theories and frameworks in different areas.

Specific Research Paradigms

As to the conceptualization of creativity, albeit some variation in scholars' understanding of what essential elements comprise creativity (e.g., Dean et al. 2006; Durand and Van Huss, 1992), the most widely adopted is Amabile's (1983, 1996) definition that creativity is the generation of novel and useful ideas in a particular domain. Accordingly, her componential model of creativity (1983), which encompasses three components of motivation, expertise, and creative thinking skills, has laid foundation for subsequent research on individual creativity (e.g., Zhang and Bartol, 2010). Additionally, recognizing joint influence of individual characteristics and situations, the interactionist approach to creativity has also been adopted in examining creative processes and performance (e.g., Zhou and George, 2001), particularly in the domains that appreciate contextual impacts (e.g., organization studies).

A vastly different approach to understanding creativity has been focused on the biological sources of creativity. Research in physiology, pathology, and neuroscience has related creativity to human physiological and pathological conditions. For example, since Sperry's (1964) seminal work on human hemispheres' association with creativity, subsequent investigations have been conducted and integrated, which suggest that both hemispheres can be synergized to enhance creativity (e.g., Mashal et al., 2007). Furthermore, the association between creativity and psychopathological states has remained a topic of interest. Nettle (2006), for example, compared schizotypy profiles in a sample of poets, artists, mathematicians, psychiatric patients, and general population. He found that creative groups were featured by the absence of anhedonia and avolition. More interestingly, different domains required different cognitive profiles in fostering creativity, with poetry and art linked to divergent thinking, and schizophrenia, disorder, and mathematics to convergent thinking.

Similarly, creativity remains a research topic in the field of applied and social psychology. Research questions concern individual cognitive styles (e.g., Torrance Tests of Creative Thinking, Kim, 2006; self-regulation, De Stobbeleir et al., 2011), affect and mood

(e.g., positive affect, Fritz and Sonnentag, 2009), stress (e.g., occupational stress, Van Dyne et al., 2002), personality (e.g., five-factor model, Dollinger et al., 2004), and so on. An example of these is studies examining the relationship between affect and creativity. Scholars have theorized and found that creativity can be associated with both positive and negative mood (e.g., George and Zhou, 2007; Nijstad et al., 2010), and emotionally ambivalent state has been linked to recognizing of unusual associations between concepts in experimental settings (Fong, 2006). At the organizational level, the linkage between positive affect and creativity has also been validated in entrepreneurs and related to organizational innovation (Baron and Tang, 2011).

Most of creativity research to date have been conducted at the individual level. These studies explored the components and antecedents of individual creativity and revealed the influence mechanism of the antecedents. Since Amabile (1983, 1996) put forward the principal component theory of individual creativity, many scholars have carried out exploratory research around motivation (Mueller and Kamdar, 2011; Dewett, 2007; Eisenberger and Shanock, 2003; Zhang and Bartol, 2010), expertise (Helie and Sun, 2010; Kaufman et al., 2009; Scott et al., 2005; Taggar, 2002; Vincent et al., 2002), and creativity skill (Runco et al., 2010; Cropley, 2006; Jung et al., 2010; Kim, 2006; Runco and Acar, 2012; Vincent et al., 2002), which were the foundation of other creative research and located at the center of the keywords network.

Furthermore, personality is a person's stable attitude toward reality, and traits expressed in the habitual behavioral patterns corresponding to the attitude. Personality has been linked to individual creativity (Mumford, 2003; Madjar et al., 2002; Taggar, 2002; Zhou, 2003). In the "Big Five" personality model, openness to experience is considered as the most relevant to creativity (Schilpzand et al., 2011). George and Zhou (2001) adopted an interactional approach to understanding how openness to experience and conscientiousness were related to creative behavior in the workplace. They proposed that openness to experience will result in high levels of creative behavior and conscientiousness in low levels of creative behavior, when the situation activates these traits. Baer and Oldham (2006) examined the possibility of a curvilinear relation between the creative time pressure employees experience at work and their creativity. The authors also examined whether the curvilinear relation between the creative time pressure and employees' creativity was moderated by employees' scores on the openness to experience personality dimension. Other factors linked to individual creativity include emotion (Fong, 2006; van Kleef et al., 2010; Akinola and Mendes, 2008; Ivcevic et al., 2007; Newton, 2013), mood (Lewis and Lovatt, 2013; Rybakowski and Klonowska, 2011), attention (Kharkhurin, 2011; Memmert, 2006), perception (Zenasni and Lubart, 2009; Forgeard, 2013), attitudes (Lee and Erdogan, 2007; Crilly, 2015), gender difference (Matud et al., 2007; Lau and Cheung, 2010; Niu and Liu, 2009), etc.

Perhaps the most rapidly growing area of research in creativity is in the field of organization and management. Keywords extracted from the database indicate two approaches based on which management scholars study creativity in organizations. First, substantial attention has been devoted to creative behaviors and processes in the organizational context. For example, considering the collaborative nature of organizations, researchers examining creativity in organizations have focused on collective processes that lead to team creativity and innovation, with focal variables such as team diversity (Bell et al., 2011), team identity (Sethi et al., 2001; Liden et al., 2014), team reflections (Somech, 2006; Hargadon and Bechky, 2006), team norms (Jiang and Chen, 2018), etc. Among these a well-developed construct linking to team creativity and innovation is team climate (West, 2002). A climate for performance excellence and one for participative safety have been found to correlate with team innovation (see Hülshager et al., 2009 for a recent meta-analysis).

Further, studies addressing organization-level creativity have attended to more macro-level factors such as marketing strategy (Kropp et al., 2006; Golovko and Valentini, 2011), industry conditions (Bisson et al., 2002), corporate strategy (Volberda et al., 2001; Chesbrough and Appleyard, 2007), firm capability (Nonaka and Toyama, 2002; Ganesan et al., 2005), entrepreneurial activities (Tang et al., 2012; Lee et al., 2004), and human resource management practices (Beugelsdijk, 2008; Chang et al., 2011). Given that research and development (R&D) units or groups are the primary innovation powerhouse in organizations, numerous studies have been conducted in examining creativity of R&D personnel or groups (e.g., Tierney and Farmer, 2004; Hirst et al., 2009; Miron et al., 2004). Moreover, creativity and performance processes by R&D organizations are illuminated with a knowledge management perspective that highlights enabling knowledge flow and access to tacit knowledge (Jackson et al., 2006).

A contextual factor identified as a major driver of creativity in organizations is leadership (Shalley and Gilson, 2004), which has been associated with creativity at multiple levels. In particular, individual creativity has been linked to such leadership styles/behaviors as empowering leadership (Zhang and Bartol, 2010), transformational leadership (Gong et al., 2009; Shin and Zhou, 2003; Hirst et al., 2009), servant leadership (Liden et al., 2014), leader-member exchange (Volmer et al., 2012), and leader supportive behavior for creativity (Amabile et al., 2004). At the team level, team creativity and innovation were found to be related to empowering leadership (Chen et al., 2011) and transformational leadership (Eisenbeiss et al., 2008; Jiang and Chen, 2018; Shin and Zhou, 2007). Finally, organization-level creativity and innovation have been examined as an outcome of transformational leadership (Jung et al., 2003; Gumusluoglu and Ilsev, 2009), visionary leadership (Strange and Mumford, 2005), ambidextrous leader behaviors (Rosing et al., 2011), complexity leadership (Uhl-Bien et al., 2007), etc. Among various leadership theories, transformational leadership appears to be the most studied in creativity and innovation research across levels. Findings generally supported its positive effects on creative behaviors and performance (e.g., Jiang and Chen, 2018; Jung et al., 2003; Shin and Zhou, 2003).

Besides leadership, another frequently studied variable in creativity and innovation research is social network. Originating from sociology, this line of thought views social structure as important for creativity, but is divided in its relative creative benefits of two opposing types of collaborative network structure: cohesion (e.g., social capital, Coleman, 1988), with actors connecting directly to each other, and brokerage (e.g., the strength of weak, diverse ties, Granovetter, 1973), with a few actors linking others who have no direct ties to each other. Likewise, most social network scholars have addressed creativity issues following the two logics, with both

cohesion (e.g., Obstfeld, 2005; Milliken et al., 2003; Uzzi and Spiro, 2005) and brokerage (e.g., Perry-Smith, 2006; Burt, 2004) perspectives having received some support.

More recent studies began to develop more complex relationships, as well as to integrate the two competing hypotheses. Lingo and O'Mahony (2010) resolved the question of how brokers generate creativity, finding that the answer lies in the integration of ideas of other collaborators by brokers through the processes of dealing with different types of ambiguities. Zhou and colleagues reported a curvilinear effect of weak ties on greater creativity, revealing a diminishing return on the number of weak ties (Zhou et al., 2009). Reconciling the cohesion and brokerage camps, Fleming et al. (2007) demonstrated the benefits of both, with brokerage leading to collaborative creativity and cohesion adding marginal benefits in conjunction with broad personal experience and external ties. Further, these authors found that cohesive networks were associated with the future use of creativity. In fact, the value of cohesive networks in the later stages of the idea journey (Perry-Smith and Mannucci, 2017), that is, after idea has been generated, has been confirmed in recent studies (e.g., Kijkuit and van den Ende, 2007; Baer, 2012).

Studies of creativity in the field of economic and urban geography have centered on the question of whether and how creativity contributes to economic growth and regional development. Departing from previous view that highly educated people are the primary determinant of local economic performance, Florida (2002) defined the creative class, formed by people who contribute to the economy by identifying problems, generating novel ideas, developing new technology, and recombining knowledge in new ways in attempt to find original solutions. In particular, these people are employed in such occupations as science, engineering, culture, arts, and entertainment. Florida claimed that it is the creative class, rather than the highly educated group, makes the most contribution to urban and regional growth. The past two decades witnessed continued advances in understanding the impact of creative class (e.g., Clifton, 2008), creative industries (Lange et al., 2008; Christophers, 2007; Stam et al., 2008), creative policies (Boren and Young, 2013), and creative economy (Wilson, 2010). A general consensus is that creativity, interplaying with cultural and ethnic diversity at multiple levels (Baycan-Levent, 2010), contributes to innovation, the development of high-technology industries, and economic growth. For example, a study of 257 regions of European Union reported that highly educated people in creative occupations contributed most to production efficiency (Marrocu and Paci, 2012). Another study of 444 city regions in eight European countries found that the creative class' specialized consumer preferences and job preferences jointly influenced the creative urban hierarchy, due to lower market thresholds for creative services and jobs (Lorenzen and Andersen, 2009).

From the perspective of social relationships, various factors are linked to creativity and innovation in contemporary urbanization processes (Scott, 2014). In a research on the primary metropolitan statistical areas in the US, density of creative workers was found to predict metropolitan patenting activity, supporting knowledge spillovers as key to boosting innovation. On the other hand, a study of Berlin's creative industries revealed a dynamic, self-governing pattern that deals with paradoxes of creativity by, for instance, communities of practice and the "culturepreneur" (Lange et al., 2008). Further, using provincial level data of mainland China, Qian (2010) reported the ratio of university students to local population to be the single most important predictor of the creative class in China. Overall, the majority of research was conducted in North America and Europe, with only a handful of studies focused on developing nations such as China (e.g., Qian, 2010).

Research on creativity also attracts scholars from basic disciplines of humanities and social science. For instance, pedagogical studies have explored various ways of learning experiences and pedagogical practices that may foster children and students' creativity. Craft and colleagues, for example, stress the importance of promoting creative learning and suggest approaches teachers can adopt to foster creativity in young learners (Chappell et al., 2009; Cremin et al., 2006). Further, Creativity is viewed as an outcome of play and learning (Samuelsson and Carlsson, 2008; Kangas, 2010). Finally, researchers have also examined assessment technique for creativity (e.g., consensual assessment of creativity) based on student writings (Kaufman et al., 2004).

In the field of arts, scholars have investigated the associations between creativity and improvisation (e.g., Montuori, 2003), imagination (e.g., Hargreaves, 2012), problem solving (Kozbelt, 2008), personality traits (e.g., openness to experience, Kaufman et al., 2016), etc. Creativity ratings have been found to vary between artist raters and non-artist raters (Serafin et al., 2011). Creativity-relevant cognitive styles (e.g., divergent thinking, Gibson et al., 2009) have been reported to differ between creative individuals (trained musicians) and general population. On the other hand, in the fields of public health, a creativity-support environment is not only conducive to employee productivity and quality (Dul and Ceylan, 2011, 2014), but also to health and well-being (Greaves and Farbus, 2006). As to creativity in scientists, Azoulay et al. (2011) compared investigators of the Howard Hughes Medical Institute (HHMI) with grantees from the National Institutes of Health (NIH); they found that HHMI investigators produced high-impact articles more likely than NIH-funded scientists. The authors ascribed the differences to HHMI's tolerance of early failure, focus on long-term success, and support of experiment. Finally, gender difference in creativity has drawn much research interest as well, with direct comparison between genders in creative tasks and performance (Kaufman et al., 2004) or testing of gender as moderating the effects of education (Ross and Mirowsky, 2006), positive affect (Filipowicz, 2006), and leadership styles (Wang et al., 2013). Studies have also examined women's creativity in terms of, for example, their diverse creative efforts and productivity (Reis, 2002).

Glossary

- Conceptual definition** The definition of an abstract construct using other abstract constructs
- Convergent thinking** Cognitive processes that result in one or a few responses to a question or stimulus
- Divergent thinking** Cognitive processes that result in numerous ideas in response to a question or stimulus
- Histriometrics** The application of quantitative analysis to data concerning historical figures
- Operational definition** The definition of an abstract construct in observable, measureable terms
- Psychometrics** The quantitative analysis of psychological measurement characteristics
- Reliability** The extent to which test scores show consistency
- Validity** The extent to which inferences drawn from test scores are appropriate for their use

Why Assess Creativity?

Creativity is a fundamental human characteristic. Evidence of creativity is apparent across time and across cultures, from ancient civilizations to 21st century endeavors. It is displayed at the individual level as well as in collaborative enterprises. The effects can be found in small ideas as well as in revolutionary advances. Creativity's contributions to all areas of human activity, including science and technology, medicine, government, agriculture, literature, the arts, and entertainment are undeniable. There is no doubt that creativity enriches and enhances human life.

Because of the breadth and depth of its impact, understanding and capturing creativity is of great interest. In order to systematically study creativity, however, one must have a means of assessing it. Assessment simply refers to the evaluation of the quality or quantity of a construct. Assessment may be based on one or more measures, or methods of measuring, or quantifying, the construct. Testing, a special case of measurement, refers to the use of standardized procedures for quantification of a construct.

Numerous techniques have been developed to assess creativity in individuals, groups, and organizations. Creativity measures are generally used to identify creative potential, to examine and understand factors that relate to creative performance, or to determine the impact of creativity interventions. The popularity and diversity of creativity assessment techniques illustrates the desire to grasp the valuable resource that is creativity.

[☆] *Change History:* August 2019: Mark Runco updated this chapter by streamlining and clarifying. Morris Stein is now cited on the different of subjective and objective frames of reference. Discussion of the 4P framework was clarified and the "potential" category (a 5th P) is now included. Discussion of Big C creativity was omitted because of discussions that it is misleading and part of a false dichotomy. The concepts "eminent" and "everyday" creativity are much more useful and thus used herein. The value of contraindicative items in personality measures is briefly described. This article is an update of M.M. Clapham, Testing/Masurement/Assessment, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 458–464.

Is Creativity Assessment Useful?

Creativity is a broadly used term. Sometimes it is used to specify a personal characteristic, such as when an individual is described as having high levels of creativity. On other occasions, it is used as a descriptor of objects or ideas, as is the case when opinions about the level of creativity displayed in artwork are offered. Yet in other applications it refers to a cognitive process, such as when a person is encouraged to use creativity in developing a solution to a problem. Although the term has varied applications, there is a shared sense of its general meaning: creativity involves producing something new and different, but also something that is effective or has value.

The meaning of creativity sometimes evokes skepticism about the possibility of assessing it. How can something that is unknown be measured? Is it possible to understand an outcome that is unforeseeable? Although the assessment of creativity may seem paradoxical, there are tests that lead to accurate predictions. This entry highlights many successful efforts to assess particular aspects of creativity, or at least creative potential, and to predict actual creative performance with reasonable accuracy. The assessment of creativity is feasible and, given the importance of creativity for individuals, society, and culture, it is critical to understanding human nature.

Defining the Construct

As with any abstract construct, a definition must first be established in order for assessment to take place. Most researchers in the field identify creativity as an ability or capacity to produce objects or ideas that are novel and purposeful. These are the two components of the standard definition. The first component is widely accepted. Most people identify creativity with originality. The second component, however, is more controversial. Why must something be appropriate or useful in order to be considered creative? Is it not the case that many creative works were deemed highly inappropriate by society at the time of inception? Creativity scholars interpret “appropriateness” and “usefulness” in the broadest sense. The original idea should have intent, purpose, meaning, in order to be creative. A unique random thought produced by an individual is generally not considered creative unless it is developed or applied with some intent or purpose. The nature of this intent may vary widely. It may consist of solving a practical problem or developing a coherent theoretical model. But it may also consist of expressing an emotional state for oneself or for others, in provoking an emotional reaction, or in presenting an alternative perspective or method. A dream you have may be very unique, so much so that you share it with friends and family who proceed to describe it as “really weird” or “bizarre,” yet this dream is not generally described as demonstrating creativity. Implementing ideas that are gathered from your dreams, however, may be associated with creativity.

This definition of creativity remains in flux. According to the standard definition, creativity is context dependent. To identify something as original, one must establish a point of comparison. Is it original in relation to the entire history of humanity? Is it original in comparison to the typical work produced by members of a certain age group within a specific culture? Or is it original within one person, a new idea for a particular individual?

To determine appropriateness, one must also consider context. Is the idea or artifact appropriate given the situation in which it was produced? Would creative works from past centuries be considered equally provocative or ingenious if they had been produced for the first time today? Morris Stein referred to the various comparisons as objective (when creative things are compared against societal norms) and subjective (when creative things are compared to the individual’s own history).

Definitions of creativity must be operational, in a scientific sense, or expressed in observable terms, in order to be useful for creativity assessment techniques. Both the purpose of assessment and the theoretical perspective of the researcher affect how a construct is operationalized. Assessing creative potential in children, for example, requires a different measurement approach than evaluating the creative contributions of eminent historical figures. Not surprisingly, a wide array of measurement techniques have been developed.

Historical Foundations

Until relatively recently, creativity was not scientifically studied. Explanations of creative outcomes, if given at all, frequently referred to supernatural influences such as muses, divine intervention and demonic powers, or to vaguely identified personal characteristics such as “giftedness” and “madness.” Many believed these external or internal forces in turn produced an “a-ha” experience in individuals that in turn propelled them to act on their ideas.

As the study of individual differences in psychological characteristics gained importance in the late 1800s and early 1900s, greater attention was directed toward the construct of creativity. Initial steps toward assessing creativity began with experimental attempts to measure fluency and imagination. Stimuli such as inkblots or word association tasks were used to assess these constructs. At this time, investigators considered creativity to be either a component of general intellectual functioning or a characteristic of personality.

J. P. Guilford is credited with directing greater attention to the scientific study of creativity and providing a framework in which to do it. His 1949 presidential address to the American Psychological Association (published in 1950) emphasized the need for psychologists to dedicate more time and effort to understanding creativity. He developed a multidimensional model

of intellect, called the structure of the intellect (SOI), that classified mental abilities by operation performed, content used to perform the operation, and the type of product produced. The broadest impact of this model was the distinction between two types of operations, convergent thinking, associated with traditional forms of intelligence, and divergent thinking, associated with creativity. Convergent thinking refers to a mental process that focuses an individual on one correct response. Divergent thinking, in contrast, is a mental process that results in a wide range of potential responses. Guilford and his colleagues identified several primary components of divergent thinking. These included fluency, flexibility, and originality. Fluency is the number of interpretable ideas produced in response to a stimulus. Flexibility refers to the number of different categories of ideas produced. Originality is the uniqueness of the ideas. Guilford and his associates designed measures to assess these components of divergent thinking.

Guilford was instrumental in popularizing both the construct and means of measuring it. Guilford believed divergent thinking was a distinguishing feature of creativity, and most current theories of creativity consider divergent thinking to be a necessary, although not sufficient, requirement for creativity. Furthermore, Guilford's conceptualization of divergent thinking influenced the development of a popular method of assessing creativity, divergent thinking tests. The divergent thinking tests developed by Paul Torrance, not long after Guilford's presidential address, continue to be some of the most widely used creativity tests worldwide, and there are several other newer batteries (e.g., the rCAB, Williams test).

Guilford's call for more research on creativity not only impacted the study of creativity as a cognitive process. His work also stimulated researchers to study creativity as it relates to personality. Of particular importance was the work conducted by researchers at the Institute of Personality Assessment and Research at the University of California in Berkeley. Both Frank Barron and Donald MacKinnon are noted for providing important insights into the characteristics of creative achievers. Their research influenced the use of personality measures as well as ratings of creative achievements for the assessment of creativity.

Since the mid twentieth century, researchers have made significant strides in the study of creativity. Numerous useful measures of creativity have been developed as a result of this research that serve, in turn, as tools for furthering our understanding of creativity. More research in this area, however, is warranted. Although great progress has been made, the scientific study of creativity remains limited relative to the importance of this construct.

Foci of Creativity Assessment

Creativity assessment tends to follow the well-known 4P framework. Thus assessments, like theories of creativity, can be grouped into four broad categories: products, people, processes, and environmental press. "Potential" has been recently added to the 4Ps and there are tests that do indeed focus on creative potential. Each of these categories necessitates that assessment efforts have a different focus. In measuring products, the emphasis is on specifying the level of creativity displayed in objects or ideas. In order to do so, type of product should be considered. Inventions, for example, may best be assessed using different methods than those applied to the evaluation of artwork. In assessing creative people, the interest is in identifying attributes associated with creative individuals. In this case, consideration must be given to the population of interest. Methods for evaluating creativity in children may differ from those for adults. In assessing processes, the researcher focuses on the cognitive functions involved during the varied stages of creativity. Divergent thinking tests offer information about relevant processes, though they also fit into the creative potential category. With environmental and press (or creative places), the interest is in determining the environmental conditions that, when pressed upon a person, enhance or inhibit creativity.

The distinction made between eminent creativity and everyday creativity is also useful. Eminent creativity is displayed by individuals of renowned fame who are recognized as creative geniuses. Figures such as Einstein, Beethoven, Cezanne, and Galileo, represent eminent creativity. In contrast, everyday creativity, is displayed in creative endeavors that have less breadth or depth of impact on society. Everyday creativity may present itself at a personal level, in original and useful responses within the range of responses typical for a particular individual, or at a social level, in original and useful responses relative to those produced within a socio-cultural group. It may consist of the development of completely new ideas or the adaptation of existing objects to meet new demands. Examples of everyday creativity include original artwork produced by children, unique dance moves that become the popular trend, or small adaptations of objects to meet current demands.

These two types of creativity, eminent and everyday, are studied using different methods. Eminent creativity is most commonly examined through case studies or historiometrics. Case studies generally produce qualitative descriptions of individuals, while historiometrics involves the quantification of information related to historical figures. Eminent creativity is interpreted as representing the highest level of achievable creative performance. It can serve as a standard to which all other creativity is compared. Its study, however, is limited by what information is available in historical records and how this information is used. The study of everyday creativity generally examines creativity of the present, which allows for the use of a broader array of assessment methods. It also relies on assessment of creativity in a relative rather than absolute fashion. In so doing, the creativity of a participant may be compared to that of others, or to one's own under different conditions, instead of to an absolute level of creativity. This relative approach to assessment acknowledges the importance of context for creativity.

The varied points of focus in creativity assessment give the sense that creativity researchers are very scattered in their study of creativity. At the same time, the availability of creativity assessment techniques that have varied points of focus provides an opportunity to examine creativity from different perspectives.

Types of Creativity Measures

Creativity measures can be classified based on their aim and content. According to a popular taxonomy presented by Dennis Hocevar and Patricia Bachelor, the primary types of creativity measures are: divergent thinking tests; attitude and interest inventories; biographical inventories; personality inventories; ratings by peers, teachers, or supervisors; ratings of eminence; judgments of products; and self-reported creative activities. A variation of this taxonomy with an added category, environmental climate inventories, is used below as a framework for discussing types of creativity tests.

Divergent Thinking Tests

Divergent thinking tests are arguably the most frequently used approach for assessing everyday creativity and creative potential. They are reliable estimates of potential in the sense that they tap originality, but they do so using open ended tasks or tests. Like all tests, they are, then, samples of behavior but not entirely representative of the entire universe of relevant capacities. As a matter of fact all tests are samples and thus estimates of potential or of future performance.

Divergent thinking tests ask participants to produce multiple ideas in response to specific stimuli. Stimuli and responses are typically either pictorial or verbal in nature. Examples of item response formats include drawing pictures using an incomplete figure, writing questions evoked by hypothetical situations, or listing possible uses for an object. The intent is to measure divergent thinking skills displayed in examinee responses. Divergent thinking tests usually assess multiple skills, as noted above, including fluency, flexibility, originality, and elaboration. Some have been used to get at problem generation skills and not just problem solving, and others have been scored for indices in the direction of effectiveness and appropriateness (Runco and Charles, 1993).

Many divergent thinking measures are available. Some of them are considered general tests that can be administered to a broad segment of the population. These include the *Torrance Tests of Creative Thinking (TTCT)*, the *Alternative Uses or Consequences* tests, *Many Titles*, *Problem Generation*, and *Realistic tests* in the Runco Creativity Assessment Battery (rCAB), and international instruments such as the Spanish *CREA* test. Other divergent thinking tests were designed with stimuli that apply to specialized fields of expertise, as is the case with the *Purdue Creativity Test* for engineers and the *Creative Engineering Design Assessment (CEDA)*. Some measures assess both divergent and convergent thinking. The *Structure of the Intellect Learning Abilities Test (SOI-LA)* is an example of such an instrument designed for the general population.

Evidence supports the contention that divergent thinking tests measure a construct that is distinct from that measured by traditional academic aptitude tests. Validity studies show that overall scores are related to creativity as measured by expert evaluations of performance as well as by creative achievements. Studies examining the ability of divergent thinking tests to predict creative performance in the long term demonstrate weaker associations than those examining associations between divergent thinking and creative performance in the present. Critics of the tests argue that their ability to predict future creative performance is limited, but predictive validity coefficients are often as higher than those from IQ tests or commonly used personality inventories.

A number of studies found that scores on different types of divergent thinking tasks, such as verbal, figural, or mathematical, do not show strong associations with each other, suggesting that domain specific skills influence test performance. The basis for this finding may lie in the fact that divergent thinking tasks require additional skills beyond divergent thinking that are linked to domain expertise, rather than in the notion that the process of divergent thinking itself is domain specific. Regardless of the reason, it appears that divergent thinking tests containing different types of stimuli and response formats are not completely interchangeable.

Overall, despite some limitations, research on divergent thinking tests indicates that they can be useful in measuring an important component of creativity, divergent thinking.

Self-assessment Inventories

Some creativity self-assessment inventories focus on characteristics of the person rather than on thinking skills demonstrated in the production of a response. Their purpose is often to tap into one's personal orientation toward creativity. There are several types of self-assessment inventories, including attitude and interest questionnaires, biographical inventories, and personality measures.

Attitude and interest inventories are based on the belief that creative individuals tend to have attitudes and interests that distinguish them from less creative individuals, such as positive inclinations toward taking risks, trying new activities, engaging in hobbies that allow exploration or self-expression, or being playful. Questions in these inventories may consist of rating scales, forced-choice options, or checklists. Examples of such inventories abound. The *Creative Attitude Survey* assesses characteristics such as imagination, creative interests, humor, and risk-taking in children. Appropriate questionnaires for adults are also available, such as the *How Do You Think?* And the *How Creative Are You?* The *Khatena-Torrance Creative Perception Inventory* has two subtests: *Something About Myself* focuses on interests and *What Kind of Person Are You?* Assesses personality characteristics. The *Creative Styles Questionnaire-Revised* integrates elements of interest and personality into one measure in an effort to assess thinking style that relates to creativity. Consistent with theories of style the focus is on "how" rather than "how much."

Biographical inventories for creativity collect information on individuals' activities and experiences that are believed to be associated with creative performance. These inventories include questions on topics such as current and past hobbies, leisure activities, family history, childhood environment, and educational experiences. In addition to questions that are biographical in nature, these

inventories sometimes include items related to interests and attitudes. The item format is usually a frequency rating scale or a checklist. Biographical inventories, such as those developed by Schaefer (the Biographical Inventory of Creativity, or BIC) or Batey, may be general or domain specific. Other inventories, based on evidence of differences in the backgrounds of creative individuals from diverse fields, are designed to apply to specific areas of expertise. The *ALPHA Biographical Inventory* from the Institute for Behavioral Research in Creativity, for example, was designed for scientists.

Interest/attitude inventories and biographical questionnaires have strengths and weaknesses. They are relatively easy to administer, and research shows that they generally have adequate reliability. Studies comparing the two types of tests indicate that interest/attitude inventories and biographical inventories are highly interrelated. This is not surprising for several reasons. First, to the extent that individuals have choices about activities, interests can affect activities. Second, as stated earlier, biographical inventories may contain interest items, and interest inventories may contain biographical items, thus blurring the distinction between the measures. These inventories, however, provide distinct information from that obtained by divergent thinking tests as indicated by relatively low associations between scores on the two types of measures. Validity studies generally provide some support for the use of interests, attitudes, and biographical information in evaluating creative potential. Some specific inventories, however, provide limited evidence of validity. Further examination of the validity of these inventories is warranted.

Personality inventories assess an individual's typical pattern of responding to situations. The characteristics assessed may be defined as personality traits or types. Most personality inventories studied in relation to creativity are questionnaires that assess an array of personality dimensions, some of which are believed to be related to creative performance. Examples of these inventories include Cattell's *16 Personality Factor Questionnaire* (16PF) and the *NEO Personality Inventory* (NEO P-RI). The *Creative Personality Scale* from the *Adjective Check List* is an example of a creativity scale that was developed from a personality inventory. Other inventories are specifically designed to assess the creative personality, as is the case with the *Cree Questionnaire*. The California Psychological Inventory now has a creativity subscale, and several measures, such as the "How Would You Describe Yourself" of the rCAB is a stand-alone survey which contains only items indicative of the creative personality. More precisely all items reflect creative personality traits, but some are worded in the negative direction (e.g., "to what degree are you a conformist?"). Such inclusion of indicative and contraindicative questions makes it unlikely that individuals will respond to all items the same way. In Psychometric terms, they minimize the chance of response sets.

A very commonly used survey focuses on the *NEO PI-R* characteristics of extraversion, emotional stability, openness to experience, conscientiousness, and agreeableness, commonly referred to as the Big 5. Much research has been conducted on the relation between these characteristics and creativity. Openness seems to be especially clearly tied to creativity.

Evidence is somewhat inconsistent, but patterns of relationships have emerged that suggest differences in personality characteristics associated with creativity in various domains. Openness to experience is, as just noted, broadly relevant, but extraversion has been found to relate positively to performance on divergent thinking tasks and in creative occupations that require social interaction. Conscientiousness appears to show a positive association with scientific creativity but not artistic creativity. Emotional instability, in contrast, has been found to be positively associated with artistic creativity. The Big 5 dimensions are very broadly defined, which limits the ability to specify aspects of personality that relate to creativity with precision. Subcomponents of the *NEO PI-R* measures as well as alternative measures, such as the dimensions of the *16PF*, have been used to examine the relationship of more narrowly defined personality characteristics to creativity. The *16PF* characteristics of persistent, adventurous, imaginative, shrewd, and self-sufficient have been related to creativity. Continued research should clarify how personality characteristics interact with domains of creative pursuit.

Self-reported Creative Activities

Self-reported assessments of creative activities focus on past activities and accomplishments. They are distinct in that they aim to specify the quantity and/or quality of creative activities, rather than personal experiences that are associated with creative performance. In other words, the focus is on the product rather than the person. Quality scores tap socially recognized creative achievements. Hocevar and Bachelor concluded that this sort of measure may be best.

These assessments usually produce counts or frequencies of real-life accomplishments believed to reflect creativity. In some applications, the accomplishments may be ranked or rated by quality, though that does bring subjectivity into play. Writing plays, stories or musical pieces; publishing research articles; being selected for art show participation, receiving special awards and recognitions for original contributions; and obtaining patents for inventions are all examples of creative accomplishments. Most of these inventories for assessing creative activities are modifications of Holland's original *Creative Activities Checklist*, from the 1960s. Newer versions include Hocevar's *Creative Behavior Inventory*, the Creative Activity and Accomplishment (from the rCAB), the Inventory of Creative Activities and Achievements (ICAAs), and the *Creative Achievement Questionnaire* (CAQ). Another inventory, the *Runco Ideational Behavior Scale* (RIBS), assesses self-rated level of engagement in ideational activity rather than actual creative accomplishments. The assumption of the RIBS is that ideas are the products of creative processes. Several investigations have found the RIBS to be a useful criterion in research on the predictive validity of divergent thinking tests. Further research on this inventory to examine its relation to other types of measures is warranted.

Self-reported creative activity measures are valuable as criteria, or standards, to which other creativity assessment instruments are compared. For example, research showing that divergent thinking tests are able to predict significant creative accomplishments provides validity for the use of divergent thinking tests as indicators of creative potential. Creative activity measures show strong

reliability in overall scores. Difficulties in their use derive from the fact that substantial creative accomplishments are limited in number for most people, making it difficult to determine distinctions in creativity, while involvement in activities may relate more strongly to interests than accomplishments. Just as it is important to keep in mind that different measures aim at process, product, personality, place, or potential, so too is it useful to keep in mind that some measures (e.g., divergent thinking or personality) are predictors, while others (the RIBS, or Holland's Creative Activity Check list) are criterion measures. This distinction was offered by Michael Wallach in 1970s but still applies today.

Ratings/Rankings/Nominations of People

In this form of assessment, a knowledgeable individual reports on other people's creativity. In the case of eminent creativity, the evaluator is usually considered an expert in a specialized field and is asked to either nominate individuals within that field whom they consider to have made important creative contributions, or alternatively to rate or rank the creative contributions of individuals in a provided list. In the case of everyday creativity, the evaluator is most typically a peer, teacher, or supervisor who knows the person well. This evaluator may be asked to provide a global rating of an individual's creativity or to rate the person on several dimensions related to creativity. The *Meeker Creativity Rating Scale* and the *Teachers' Evaluation of Students' Creativity (TESC)* were developed to rate students on creativity-related characteristics, while the *Parental Evaluation of Children's Creativity (PECC)* asks parents to assess their children's idea generation. Teacher, peer and supervisor ratings, rankings and nominations have been used as criteria for evaluating the validity of creativity tests and the effectiveness of creativity interventions. Research shows that multiple evaluators with knowledge of an individual and information on the rating criteria provide similar creativity ratings. Some critics, however, question the level of validity of these assessments. Whenever judges are involved, there is subjectivity which creates the possibility of halo effects or systematic bias. The key concern is that of generalization. Certain groups of judges may give reliable ratings but this does not mean that what they think (i.e., their ratings) will generalize to all groups of judges.

Judgments of Products

Some of these same concerns apply to ratings of creative products. In this assessment approach, knowledgeable individuals rate ideas or artifacts on their level of creativity. One or several questions may be used in the rating scale. The most popular and sound method for rating creative outcomes is the *Consensual Assessment Technique*. In this method, multiple expert judges rate the creativity of an observable response within a particular domain. Artists rate paintings or collages, writers rate stories, mathematicians rate math problems, and so on. The average rating across experts is then used as the measure of creativity. Experts are also asked to rate other dimensions of the product such as technical quality or attractiveness to ensure discrimination between dimensions. Research shows that this method generally results in high agreement among raters on creativity and clear distinction of creativity ratings from ratings on alternate dimensions. The consensual technique, with its use of multiple raters, reduces error due to idiosyncrasies of raters. Judgments of products using the consensual assessment method have been used effectively as criteria in many creativity studies.

Creative Climate Inventories

A relatively recent approach in creativity assessment is to examine the extent the environmental climate supports creativity. Several measures have emerged which assess factors in the environment that may promote or inhibit creative performance. The purpose of the *KEYS: Assessing Climate for Creativity* instrument is to assess stimulants and obstacles to creativity in work environments. Questions in the instrument ask employees to rate their work environment on a number of dimensions believed to relate to creative production. The instrument can be used by employees at various levels in the organization, and scores show strong evidence of association with ratings of organizational creativity. The *Team Climate Inventory (TCI)* is intended to assess climate for innovation in work teams. The instrument measures four dimensions of team performance: vision, participative safety, task orientation, and support for innovation. Tudor Rickards developed a measure that focuses on barriers within teams and organizations, which make sense because organizations can do things to support and inhibit creativity. Both should be assessed. Research to date indicates that these dimensions are related to perceived team performance on creative projects. These measures are an important contribution to the assessment of creativity (see [Table 1](#)).

Challenges and Opportunities

The various approaches to creativity assessment are quite distinct. Associations between scores on the diverse types of measures indicate that they are not assessing identical constructs. This poses challenges in the study of creativity.

First, choices need to be made in terms of appropriateness of measures for the intended purposes of assessment. Using an instrument for predicting creative potential is quite different from using a measure to evaluate current levels of creative performance or

Table 1 Partial list of creativity measures.

<i>Name of test</i>	<i>Authors/date</i>	<i>Type of test</i>
16 Personality Factor Questionnaire (16PF)	Cattell, R. B. (1993)	Personality
Abbreviated Torrance Test for Adults (ATTAs)	Goff, K. and Torrance, E. P. (2002)	Divergent Thinking
Adjective Checklist: Creative Personality Scale	Gough, H. and Heilbrun, A. (1965)	Personality
ALPHA Biographical Inventory	Institute for Behavioral Research in Creativity (1972)	Biographical
Alternative Uses	Christensen, P. R., Guilford, J. P., Merrifield, P. R., and Wilson, R. C. (1960)	Divergent Thinking
Biographical Inventory of Creativity	Schaefer, C. E. (1970), later Batey	Biographical
Consensual Assessment Technique	Amabile, T. (1982)	Judgment of Products
Consequences	Christensen, R. R., Merrifield, P. R., and Guilford, J. P. (1958)	Divergent Thinking
CREA	Corbalán, F. J., Martínez, F., Donolo, D., Alonso, C., Tejerina, M., and Limiñana, R. M. (2003)	Divergent Thinking
Creative Achievement Questionnaire (CAQ)	Carson, S., Peterson, J. B., and Higgins, D. M. (2005)	Activities/Accomplishments
Creative Activities Checklist (Holland, Hocevar)	Paek and Runco (2017)	Activities/Accomplishments
Creative Attitude Survey	Schaefer, C. E. and Bridges, C. I. (1970)	Interest/Attitude
Creative Behavior Inventory	Hocevar, D. (1979)	Activities/Accomplishments
Creative Engineering Design Assessment (CEDA)	Charyton, C., Jagacinski, R. J., and Merrill, J. A. (2008)	Divergent Thinking
Creative Styles Questionnaire-Revised	Kumar, V. K., Kemmler, D., and Holman, E. R. (1997)	Interest/Attitude/Personality
Cree Questionnaire	Thurstone, T. G. and Mellinger, J. (1986)	Personality
Group Inventory for Finding Interests (GIFFIs)	Davis, G. A. and Rimm, S. B. (1980)	Interest/Attitude
How Creative Are You?	Raudsepp, E. (1979)	Interest/Attitude
How Do You Think?	Davis, G. (1975)	Interest/Attitude
KEYS: Assessing Climate for Creativity	Amabile, T. M., Conti, R., Coon, H., Lazenby, J., and Herron, M. (1996)	Creative Climate
Khatena-Torrance Creative Perception Inventory	Khatena, J. and Torrence, E. P. (1998)	Interest/Attitude/Personality
Meeker Creativity Rating Scale	Meeker, M. (1987)	Ratings/Rankings/Nominations
NEO Personality Inventory (NEO PI-R)	Costa, P. T. and McCrae, R. R. (1992)	Personality
Parental Evaluation of Children's Creativity (PECC)	Runco, M. A. (1989)	Ratings/Rankings/Nominations
Purdue Creativity Test	Lawshe, C. H. and Harris, D. H. (1957)	Divergent Thinking
Runco Ideational Behavior Scale (RIBS)	Runco, M. A., Plucker, J. A., and Lim, W. (2001)	Activities/Accomplishments
Structure of the Intellect Learning Abilities Test (SOI-LA)	Meeker, M. and Meeker, R. (1975)	Divergent Thinking
Teachers' Evaluation of Students' Creativity (TESC)	Runco, M. A. (1987)	Ratings/Rankings/Nominations
Team Climate Inventory (TCI)	Anderson, N. and West, M. A. (1996)	Creative Climate
Torrance Test of Creative Thinking: Figural (TTCT-Figural)	Torrance, E. P. (1966)	Divergent Thinking
Torrance Test of Creative Thinking: Verbal (TTCT-Verbal)	Torrance, E. P. (1966)	Divergent Thinking

one that was designed as a criterion measure. A set of guidelines to assist creativity measurement users in the selection of instruments appropriate for their purposes would be quite practical.

Second, confusion can arise regarding what different assessment techniques actually measure. There is a tendency for the interpretation of the meaning of test scores to extend beyond their actual meaning. Divergent thinking, for example, is frequently equated with creativity when it more accurately represents just one component of creativity, ideation. Creativity interest inventories may be interpreted as instruments for identifying creative people when they assess relatively limited aspects of individuals that may relate to increased likelihood of creative performance. In either of these examples, additional conditions must exist for creativity to be displayed. The confusion about the meaning of scores can lead to erroneous inferences being drawn from research results.

Third, the identification of appropriate criteria for the study of creativity is difficult. Frequently used criteria include the RIBS, ratings of creative products, or scores on creative achievement and activity measures. As mentioned above, divergent thinking is occasionally used as a criterion but this is a mistake. The ideation displayed in these tests is produced within a testing condition that generally does not incorporate situational or motivational variables that affect creativity; performance on these tests does not mimic creative performance in real life. Tests of divergent thinking are predictors, or estimates of potential. Other potential criteria, such as ratings of creative products or counts of creative achievements pose their own problems. Obtaining meaningful ratings of creative products with high psychometric quality can be difficult and time consuming. Furthermore, the products that are rated may not be representative of one's creative capabilities across time and across domains. Similarly, measures of creative achievements may not be representative in that achievements might not be fully realized at the time of assessment. Using multiple criteria can compensate for limitations in any one assessment approach, and is therefore highly valued in research studies.

While challenges exist, the various approaches for assessing creativity also provide opportunities for integration of the creativity literature. Although there is some variability in the components specified by each of the available models of the creative process, they share basic elements. These include creative thinking skills, personal characteristics, and environmental factors that promote creativity. The tendency to study factors that influence these components individually prohibits a full understanding of the creative

process. There may be very complex interrelationships between the various factors involved in creativity and the diverse types of creativity. For this reason, studying one factor at a time using one measure of creativity may be misleading. Research using different types of creativity measures to assess the multiple aspects of creativity can illuminate the interrelationships between components of creativity. The variety of creativity measures that exist, therefore, comprise an important toolbox that can be used for integrating research findings into a coherent theoretical framework.

Introduction

For millennia, human beings have pondered the nature of creativity. Much of this speculation has served as commentary on the spectacular achievements of our species, with creators themselves often furnishing detailed descriptions of their own processes and motivations (Ghiselin, 1952). Until recently, theoretical conceptions of the nature of creativity have been rooted in first-person introspection or on case-study – like familiarity with the works of a small number of creators. However, in the last half century or so, scholars and researchers – mainly from psychology, but from other domains as well – have tried to advance on this armchair tradition (Kaufman and Sternberg, 2010; Runco, 2007; Sternberg, 1999). They have applied more rigorous research methodologies, increasingly sophisticated analytic techniques, far richer datasets, and (often) a pragmatic, applied orientation. Importantly, their approaches have also been informed by and grounded in knowledge from other relevant domains, including other sub-disciplines within psychology. The resulting surge of research activity has yielded a diverse array of theoretical approaches for understanding creativity. The purpose of this article is to describe contemporary theories of creativity and to offer a critical yet constructive appraisal of current theories and their promise for continued discovery about the nature of creativity.

Ways of Understanding Theories of Creativity

Pluralism

A generous-spirited way of understanding contemporary research on creativity is to emphasize *pluralism*, whereby a robust understanding is achieved through a multitude of perspectives, each characterized by different assumptions, definitions, and methods, operating at different levels of analysis, and making connections with various other disciplines. When faced with an array of perspectives, the need to characterize commonalities among theories, while still recognizing differences, becomes apparent. Here, to set the

[☆]Change History: May 2019, Aaron Kozbelt updated the text throughout the article.

This article is an update of A. Kozbelt, Theories of Creativity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 473–479.

stage for main categories of creativity theories, four thematic frameworks are discussed: a more scientific versus a more metaphoric quality, a purely theoretical versus applied focus, level of creative magnitude, and emphases among the so-called six P's and five A's of creativity. While there is some overlap among these themes, they may be regarded as largely independent, so that any particular theory might partake any combination of the levels of these frameworks.

Scientific Versus Metaphoric Theories

One common distinction, in many areas of study, is between more overtly scientific theories versus more metaphorical ones. Scientifically-oriented theories have an underlying goal of mapping the empirical reality of creative phenomena and aspire to traditional scientific standards: a search for objective truth, generating empirically falsifiable hypotheses, and developing formal or computational models. In contrast, metaphorically-oriented theories offer a more speculative stance focusing on provoking new understandings and possibilities and offering a moderating counterbalance to the stark empirical focus of scientific theories. Such theories are of maximal use when they balance speculation with agreed-upon methods and standards of empirical exploration and peer review. The varied, complex, and interdisciplinary nature of creativity naturally lends itself to exploration by both kinds of theories.

Theoretical Versus Applied

Creativity researchers have varied goals. For some, it is understanding creativity as its own phenomenon, in a disinterested, 'pure' scientific way, without overt interest in the practical applications or implications of discoveries. Others' goals are more pragmatic – usually, to increase creativity by identifying factors associated with its natural development (and to create environments with such characteristics) or by designing specific interventions to promote creative thought. While some theories focus more on one than the other, most have implications for both pure and applied research.

Levels of Creative Magnitude

Another framework concerns what may be called level of creative magnitude. Not all instances of creativity are equal. A standard distinction is between 'Big-C' (truly great, history-making instances of creative breakthroughs among eminent individuals) versus 'little-c' creativity (a private but novel insight or realization in an ordinary person). Kaufman and Beghetto (2009) proposed two additional categories of creative magnitude: a 'mini-c' category provides more room for subjective or personal instances of creativity; a 'Pro-C' category allows for professional-level creators who have not yet attained eminence, but who are well beyond little-c creators in knowledge, motivation, and performance.

A focus on a particular magnitude will constrain a researcher's basic questions, sources of data, and methodologies. Widely acknowledged Big-C or Pro-C achievements are more often approached by the analysis of archival data (creative products, laboratory notebooks, sketches, etc.) or by carefully targeted laboratory or case study investigations on select individuals. In contrast, little-c and mini-c creativity lend themselves to more varied methods, including laboratory experiments, paper and pencil surveys and inventories, microgenetic studies of creative behaviors, and introspective self-reports of the subjective aspects of the creative experience.

The Six P's and Five A's of Creativity

Another common framework, described by Kozbelt et al. (2010), involves the so-called six P's of creativity: *process*, *product*, *person*, *place*, *persuasion*, and *potential*. Since this alliterative scaffold nicely organizes many issues in the study of creativity, it is a useful way to compare the scope of different theories.

Theories that focus on the creative process aim to understand the nature of the mental mechanisms that occur when a person is engaged in creative thinking. Process theories typically identify different specify stages of processing or particular mechanisms as the components of creative thought. Another approach focuses on creative products: works of art, inventions, publications, etc. Products can usually be counted, permitting quantitative objectivity, and they are often available for judging, so inter-rater reliability can be readily determined – two substantial advantages; however, products themselves say little about their creators or the creative process that engendered them.

Studies of the creative person (or personality) tend to focus on identifying and understanding individual difference traits that are associated with creativity, such as intrinsic motivation, wide interests, openness to experience, and autonomy; some traits also seem more pervasive either among persons in artistic or scientific domains. The actualization of creativity also depends on the place or setting in which an individual resides. Research on place factors is especially useful in defining such interactions between persons and environments, which tend to be optimal for creativity when there are opportunities for exploration and independent work and when originality is valued.

Another view describes creativity as persuasion: creative people change the way others think, so they must be persuasive to be recognized as creative. This notion shares assumptions with a number of theories, in which persuasive individuals are the ones who influence the direction taken by a domain. Finally, the notion of creative potential addresses the need to examine and understand the latent capacity for creative thought in children and others, who may have what it takes ultimately to be creative, but who require

educational opportunities or other support before they can do so. Obviously, the goal of realizing creative potential is a major goal in education, so studies of creative potential often have a strong practical focus.

Beyond the classic framework of the P's of creativity, a more recent and roughly analogous model, Glăveanu's (2012) so-called five A's of creativity, has also been proposed. The five A's (and their P analogues) are: actor (person), action (process), artefact (product), audience (press), and affordances (also press). While there is some degree of overlap, the five A's framework places greater stress on socio-cultural modes of creativity and distributed cognition, compared to the emphasis on the individual within the P's framework.

Categories of Theories of Creativity

Overview

Ten major categories of theories are now described: *Developmental*, *Psychometric*, *Economic*, *Stage and Componential Process*, *Cognitive*, *Problem Solving and Expertise-Based*, *Problem Finding*, *Evolutionary*, *Typological*, and *Systems*. The goal is to provide a big-picture overview of each type – for more detail, see Kozbelt et al. (2010). Most theories described here have been discussed in the literature for at least several decades, boast considerable research support, and span multiple P's (and A's), levels of analysis, and methodologies. Excluded are theories that are limited to understanding a specialized subtopic – like creativity's relation to mental illness or to personality, its biological underpinnings, cultural differences, and so on.

Developmental Theories

Developmental theories pragmatically aim to understand the roots of creativity, as suggested by the backgrounds of Big-C creators, but they also often suggest how to design environments to fulfil creative potential (Feldman, 1999). They mainly emphasize the person, place, and potential aspects of creativity (and analogous A's), and range from mini-c to Pro-c. Early developmental theories were devised by examining the lives and backgrounds of eminent creative persons; these suggested that particular developmental experiences were correlated with later creativity, such as exposure to diverse experiences, and not being overly restricted.

Other theories focus on family structure (e.g., birth order, ordinal position within the family, age interval between siblings, etc.). For instance, evidence suggests that middle children often rebel against their parents and the status quo, to attract attention away from older siblings whose maturity earns them praise. Rebellion may occur within the context of the family, in one's thinking, or, during adulthood, in artistic or scientific revolutions (Sulloway, 1996).

Longitudinal methods provide another powerful perspective on development. Findings from this tradition indicate that during their childhoods, the truly gifted also had the support to make cognitive and emotional transitions – one from general to creative talent, and the other from capability to a motivational state which leads directly to actual achievement. Such studies reinforce developmental theories of creativity that consider cognitive processes, motivation, affect, and personality.

Psychometric Theories

Psychometric theories focus on measurement and thus inform all other creativity theories (Guilford, 1968). Emphasizing products (or artifacts) over the other P's (or A's), they range from little-c to Big-C creativity and are concerned, among other things, with the reliability (agreement or consistency of measurement) and validity (accuracy) of assessment, which are issues in all creativity research. Besides establishing basic principles of the measurement of aspects of creativity, psychometric theories have also addressed issues like how creativity differs from intelligence, the relation between performance on convergent thinking (one right answer) tasks and divergent thinking (many correct answers) tasks, and the extent to which creativity is rooted in particular domains of activity (like music, mathematics, or writing) versus being a domain-general ability.

Economic Theories

Another category of theories draws on economic metaphors (Rubenson and Runco, 1992). The macro-level quality of these theories encompasses all of the P's (and A's) except process (or action), and spans little-c to Big-C creativity. There are several economic or investment theories of creativity. Some describe the market for creativity, which illustrates macro-level processes and interactions involving the allocation of resources. Markets can provide benefits to certain behaviors or impose costs upon them, which can be defined in psychological terms. Other research has examined the market for creative behaviors, defining a creative class or segment of society and arguing that a key component of the market for creative work is tolerance; unconventional people sometimes need to be tolerated, and creative societies do a good job of that. Other work has emphasized investments in creative behavior, in that creativity can result when a person buys low (i.e., invests in an idea which is currently unpopular) and then sells high (i.e., the idea gains respect).

Stage and Componential Process Theories

As noted earlier, many models of the creative process have been proposed. Some attempt to understand the creative process in terms of stages, which can be sequential or recursive; others focus on underlying componential cognitive processes. Such models range from mini-c to Big-C creativity and obviously emphasize process (or action) over the other P's (or A's).

Stage theories usually try to understand how moments of creative insight occur, typically by positing a particular sequence of processes – for instance, [Wallas's \(1926\)](#) venerable model of preparation (gathering information and defining a problem), followed by incubation (taking some time away from the problem), followed by illumination or insight (having a sudden realization of the answer), followed by verification (applying the solution). Since the strict linearity of such models has been largely discredited, more recent models have acknowledged the need for recursion, whereby an individual may cycle through the stages multiple times, in various combinations.

As an alternative to sequential or recursive stages, some recent theories have defined the creative process in terms of component mechanisms or processes, which operate in a more inter-connected manner. Various componential frameworks emphasize factors like domain-relevant skills, cognitive style, knowledge of heuristics for generating novel ideas, attitudes towards specific tasks, and perceptions of one's motives, and how these components interact to generate novelty.

Cognitive Theories

Cognitive theories emphasize the creative process (action) and person (actor): process, in emphasizing the role of cognitive mechanisms as a basis for creative thought; and person, in considering individual differences in such mechanisms. Some cognitive theories focus on universal capacities, like attention or memory; others emphasize individual differences, like those indexed by divergent thinking tasks; some focus on conscious operations; others, on preconscious, implicit, or unintentional processes.

One classic cognitive theory, by [Mednick \(1962\)](#), holds that creative insights result from associative processes in memory. In this view, ideas are chained together, one after another, and more remote associates tend to be more original. This perspective argues that more creative individuals have flatter hierarchies of associations than less creative individuals; thus, more creative people have many more relatively strong associates for a given concept, rather than only a few. This is thought to provide greater scope for the simultaneous activation of far-flung representations, which some believe is an important engine of creative thought.

Along similar lines, another cognitive theory focuses on how concepts are combined to generate novelty. Research suggests that conceptual combination – bringing two different sets of information together – is often involved in creative ideation, that original insights are more likely when two disparate features are brought together, and that connections between these concepts might only be seen at a very high level of abstraction. This kind of thinking has been called metaphoric logical, the idea being that something like “angry weather” is only comprehensible in a non-literal fashion. Such processes may suggest creative alternatives to well-worn lines of thought.

More generally, research in the ‘creative cognition approach’ tradition, another important contemporary view of creativity developed mainly by [Finke et al. \(1992\)](#), has likewise emphasized ideas drawn from cognitive psychology. These include conceptual combination, conceptual expansion, creative imagery, and metaphor, all of which are used to understand how individuals generate ideas and explore their implications in laboratory-based invention and design tasks. Such processes are thought to play out in two fundamental regimes of thought: generating ideas and exploring their implications. In practice, the two are strongly interleaved and combined in the ‘geneplore’ model of creative thought (from *generate* + *explore*).

Finally, metacognitive processes (thinking about one's own thinking) are also frequently tied to creativity. Many tactics for increasing creative problem solving have been proposed and popularized, including “think backwards,” “shift your perspective,” “put the problem aside,” and “question assumptions.” Tactical thinking is especially useful for programs designed to facilitate creative problem solving since they are a function of conscious decisions and can be employed whenever necessary.

Problem Solving and Expertise-Based Theories

A related major category of creativity theories, again drawn from cognitive psychology, emphasizes problem solving processes and expert knowledge ([Weisberg, 2006](#)). This is largely a theory of the creative person (actor) and process (action): person, in emphasizing domain-specific expertise as necessary for significant creative achievements; process, in emphasizing how traditional cognitive psychological concepts like problem representations and search through problem spaces explain how people devise creative solutions to problems. Such principles can be readily applied to ill-defined problems, which are under-specified and which admit multiple good enough solutions, rather than one uniquely correct answer. Ill-defined problems can often be broken into several well-defined problems, which can then be solved in familiar ways. Moreover, one can search not only for a solution, but also for an appropriate way to formulate a problem.

The problem solving/expertise view boasts support from many lines of evidence. Many of the processes and structures described in the creative cognition approach can be straightforwardly related to those of the problem solving/expertise view. Archival studies of great creators reinforce the importance of domain-specific knowledge for high-level creative achievement, for instance in the ‘ten-year rule,’ whereby at least a decade of intensive work in a domain is required before a creator produces any original works of lasting value. The archival study of creative episodes taken from the notebooks of eminent scientists has also generated a number of computational models of the creative process, which have replicated many major scientific discoveries.

Overall, the problem solving/expertise view regards creativity as a largely rational phenomenon, in being amenable to rigorous empirical study by researchers, and to meaningful strategic guidance and long-term learning by creators themselves. Thus, another advantage of this view is pragmatic: its foci are strategic factors that individuals can partly control; at the same time, the problem solving/expertise view acknowledges that Big-C problems are extremely difficult.

However, this view has some limitations. For instance, expertise is a necessary but not sufficient condition for Big-C creativity; many other factors also contribute to high-level creativity. Also, the expertise view arguably overstates the role of cumulative deliberate practice, at the expense of talent. Finally, some have criticized the computational approach to creativity as fundamentally misguided.

Problem Finding Theories

Problem finding, another influential view of creativity, originally postulated by [Getzels and Csikszentmihalyi \(1976\)](#), can be seen as a reaction against the traditional problem solving approach to creativity. The problem finding view holds that the problem solving view is inadequate to explain how creators come to realize that a problem exists in the first place and how they are motivated to bring their subjective experience to understand the problem. Problem finding is often regarded as independent of problem solving, and it is mainly as a theory of the creative process (action); it can also be seen as a theory of the creative person (actor). In terms of creative magnitude, problem finding is often construed as an instance of mini-c creativity, though there is also room for higher levels.

Early research on problem finding focused on understanding the exploratory behavior of creative visual artists, with a strong emphasis on their motivational factors and existential concerns. Since problem finding is more subjectively-oriented and harder to define than problem solving, it is more difficult to cite evidence definitively bearing on problem finding, either pro or con. The problem finding view may also overemphasize on-line discovery, at the expense of considering habitual behavior patterns.

Overall, the distinction between the problem solving and problem finding frameworks may be less due to substantive differences between the theories and more a matter of the taste of individual scholars. In any case, more recent models have often focused less on such labels and more on the nature of the underlying processes, using terms like 'problem construction' to encapsulate the constellation of processes involved in devising a creative solution to an ill-defined problem.

Evolutionary Theories

Researchers have proposed several theories of creativity drawing on ideas from evolutionary biology. Of these, a strong candidate for the most comprehensive general theory of creativity is the Darwinian model of [Simonton \(1999\)](#), which, to varying extents, covers all of the P's (or A's) of creativity: person and potential, in identifying dispositional and developmental idiosyncrasies associated with the realization of initial creative potential into actual creative achievements; process, in laying out a two-step model of ideation and elaboration, in which chance combinations of ideas play a paramount role and whose complexities are hard to control; product, in noting sometimes unreliable initial assessments versus longer-term stable judgments of creative artifacts; place, in identifying social factors leading to outstanding creativity; and persuasion, in emphasizing how social dynamics establish verdicts of creative outcomes. More than any other theory, Simonton's Darwinian view aims to understand the nature of genius, eminence, and Big-C achievements.

The basis of the Darwinian model is a mental process involving the blind generation and selective retention and elaboration of ideas. Ideas are combined in some blind fashion, typically below the threshold of awareness; the most interesting combinations are then consciously elaborated into finished creative products; these in turn are judged by other people. This process can be elaborated into a mathematical model that accurately describes how creative productivity unfolds over the lifespan, and a great deal of quantitative archival evidence supports the predictions of the theory. Indeed, the model's quantitative basis gives it a rigor unsurpassed by any other major theory of creativity.

The Darwinian view has major psychological implications. Given the complexity of the creative process, creators should have little control over guiding the progress of their works. Creators should also not be particularly good judges of their ideas or works. Moreover, once works are finished, creators have little control over their fates, since this is a social judgment; thus, mass-production is the optimal strategy for those seeking eminence.

Despite its comprehensiveness, the Darwinian view can be critiqued along several lines. It arguably over-emphasizes the role of chance factors in explaining creativity. Also, despite its mathematical parsimony, process particulars are left unspecified. Moreover, an array of theoretical arguments has also been offered that dispute fundamental premises of the Darwinian view, as well as objections based on empirical data that do not conform to the predictions of the theory. Finally, however well the Darwinian view works as a first approximation to many phenomena in the study of creativity, it explains little of the considerable error variance in relations between productivity and eminence, age and productivity, the production of masterworks versus minor works, or in creators' varied career trajectories. Understanding such individual differences is a focus of the next category of theories.

Typological Theories

One approach to understanding variation in creators' personalities, working methods, and career trajectories has been to posit typologies of creators, who differ in systematic ways ([Galenson, 2006](#)). A number of such frameworks exist, many of which

have elements in common; however, at least as often, they differ in their particulars, so that different typologies can be difficult to relate to one another. As a group, however, typological theories differ from the nomothetic (or universalist) emphasis of other theories, in aiming to explain variability among creators rather than overall trends. Various typologies touch on aspects of all of the P's (or A's) and levels of creative magnitude.

Typologies are most often cast as a set of categories, often construed as mutually exclusive. This is convenient for readily understanding the big picture, but it may be misleading when a typology is generalized too broadly, or individuals are made to try to fit into a category they may only partially exemplify; this latter point also raises the issue of potentially poor reliability in categorizing individual creators. Setting up mutually exclusive categories is also limited in precluding multi-dimensionality, which can seem antithetical to the multi-faceted nature of creativity.

An alternative is to cast individual differences not in terms of discrete categories, but multiple continuous dimensions, which creates a space of possibilities in which a particular creator can be located. Going even further, at their best, typological theories not only note the factors along which creators differ but attempt to relate these factors to each other across multiple levels of analysis.

Considered as such, typological theories are promising for achieving an integrated, multi-level understanding of creativity, as research moves forward. A key virtue of such an approach is the potential rapprochement between historically opposed camps in the study of creativity, such as the problem solving/expertise and Darwinian approaches, both of which can be at least partly absorbed into typological models. It is debatable whether such a unified theory of creativity is possible – or even desirable, from the standpoint of pluralism raised at the outset of this article. However, taking into account the unique and highly varied characteristics of individual creators is an issue that any comprehensive account of creativity ultimately has to face. These higher-level themes are also characteristic of our final category of models: 'systems' views of creativity.

Systems Theories

Some of the broadest and most ambitious theories of creativity take the view that creativity is best conceptualized not as a single entity, but as a phenomenon emerging from a complex system with interacting subcomponents. Such 'systems' theories take a broad and often quite qualitative contextual view of creativity. A number of such theories have been proposed, almost all of which address each of the P's (and A's), though with different emphases, depending on the relevant level of creative magnitude.

One influential systems theory, devised by Csikszentmihalyi (1988), takes as its starting point not the question, "What is creativity?" but rather, "Where is creativity?" In this view, creativity emerges via three interacting components: 1) the domain, or body of knowledge that exists in a particular discipline at a particular time; 2) the individual, who acquires domain knowledge and produces variations on the existing knowledge; and 3) the field, comprised of other experts and members of the discipline, who decide which new works are worth preserving for the next generation. Each has a role in determining what counts as creative.

This perspective involves multiple factors and takes a very broad view of creativity, emphasizing the ubiquitous role of place (or environment) among the P's, especially for Big-C achievements. It also elaborates the nature of the creative person by detailing how individuals other than the creator contribute to the emergence of creativity and de-emphasizes internal processes and individual contributions, placing more emphasis on collaborative creativity and the societal conditions which can best foster genius. It likewise highlights issues like the importance of 'gatekeepers' like journal editors and gallery owners, who play a major practical role in determining which contributions will be given the opportunity to be judged as creative.

This framework has many advantages, not the least of which is acknowledging the importance of extra-personal, socio-cultural factors, which were previously underemphasized in creativity research. However, the qualitative nature of the model makes it difficult to test hypotheses unambiguously, and its strong inter-disciplinarity could be a pragmatic roadblock – though for a rich understanding of creativity, many more variables and levels of analysis need to be considered besides a quantitative, empirical approach to individual traits.

Another view, pioneered by Gruber (see Wallace and Gruber, 1989), is the 'evolving systems' approach. This has mainly been applied to understanding the unique attributes of the creative person, via detailed archival case studies, which are motivated by a particular question – for instance, how Darwin devised the idea of evolution by natural selection. Such case studies focus less on understanding the particulars of one creative act than on how those particulars fit into an individual creator's goals, knowledge, and reasoning, plus larger social forces and creative paradigms.

The emphasis of the evolving systems approach is on dynamic, developmental processes that play out in complex ways and contexts, over varied timescales. Several key concepts provide a framework for understanding creative individuals in the midst of such complexity. One is the notion that great creators use an 'ensemble of metaphors' in their thinking, which together characterize a developmental process leading to creative meaning-making. Another is that of a 'network of enterprises,' a system of goals that describes how an eminent creator may work on seemingly disparate topics and projects, consecutively or concurrently, and continually evolve a sense of the relations between the topics. Such analyses put considerable interpretive pressure on researchers, particularly in absorbing the details and global qualities of a large amount of material and in avoiding pat, hindsight-biased conclusions about a creator's entire career. However, if used judiciously, this method has the potential to characterize creators with a qualitative richness and rigor unmatched by any other approach.

Future Directions for Creativity Theories

Pluralism, Again

At the outset of this article, pluralism was put forth as a way of celebrating the diversity of creativity theories currently in the literature. The principle of pluralism may also prove useful in guiding future directions as scholars develop, refine, and connect theoretical perspectives. Such connections between different theoretical perspectives could potentially lead to attempts at grand, unified theories of creativity; however, unified theories or not, making connections would strongly benefit creativity research anyway, as researchers better situate their theories in the broader theoretical and empirical character of the domain, acknowledging and incorporating the plurality of perspectives that have taken root and flourished. This applies to all the principal frameworks outlined earlier – including the six P's and five A's of creativity, the various levels of creative magnitude, a pure research versus applied focus, and a more scientifically-oriented versus metaphorically-oriented approach.

What Do We Know? A Critical Reconsideration of Theories of Creativity

In the light of the preceding exposition and discussion of current theories, let us revisit a theme somewhat related to the scientific-metaphoric distinction: the question of what researchers have actually learned about the nature of creativity, and what role theories have played in that process of discovery.

Creativity researchers work in an inherently uncomfortable position. At any level of magnitude, creativity by definition involves variety and unpredictability, which raises a host of conceptual, methodological, and measurement complications. Beyond that, a more subtle, but also more insidious, issue is that creativity as a topic of study is not some independent natural science phenomenon, whose physical workings can gradually be understood in reasonably objective terms. Rather, creativity is an all-too-human enterprise, one which our most illustrious forbears – Newton, Michelangelo, Mozart – probably had a far richer experience of – and, perhaps, deeper knowledge of – than virtually any contemporary creativity researcher.

This observation presents enormous conceptual and practical difficulties. This is especially true for researchers of Big-C Creativity, who must grapple with phenomena of unmatched depth, richness, and complexity, and who must achieve some multidisciplinary understanding of the particulars of the domain of expertise of their subject. (The issue is somewhat less threatening in the realm of little-c creativity, since the creativity of researchers can – hopefully – reasonably be expected to exceed that of most of their subjects.) It is an open question, to what extent any contemporary theory is a substantive improvement on the best armchair speculation antedating the modern psychological approach to the study of creativity. Indeed, from a hard-nosed, ultra-scientific perspective, many so-called 'theories' of creativity are arguably not well articulated or substantive enough to be informative about the phenomenon one way or the other.

The written record of eminent creators' armchair theorizing about creativity thus stands as an elephant in the creativity theory room. If the study of creativity is to be scientifically respectable, it surely needs to go beyond what could merely be arrived at by intuition, like any mature empirical discipline. This includes making falsifiable and counterintuitive predictions (not just common-sense post-dictions), as well as making contact with well-developed neighboring domains and spanning multiple levels of analysis. Doing so need not imply a single unified theory of creativity or an abandonment of metaphorically-oriented theories, but it does require high critical standards. A well-developed theory of creativity also does not entail making error-free predictions. In many ways, the domain of creativity research is more similar to contingency-intensive disciplines like history or biology, both of which have seen the development of rigorous, beautiful theories with great explanatory power, even if they cannot predict the future in great detail.

In considering the prospects and nature of reasonably rigorous theories of creativity, several criteria for the value of a theory are worth remembering. One is accuracy, or correctness: does a theory make good predictions and yield reliable knowledge about a phenomenon? Another, however, is fruitfulness: the capacity of a theory to disclose new phenomena or relations among phenomena and to generate testable hypotheses. Some very accurate theories are sterile; some wrong theories are nevertheless very generative. In the history of science, many wrong ideas have been enormously useful, if only because the process of disproof can lead to greater knowledge and integration. For a topic like creativity, where precise predictions may not be a reasonable goal, fruitfulness may be the better criterion of a theory's usefulness.

How have current theories of creativity fared by these two criteria? Given the complexity of the phenomena of creativity, it is encouraging that many contemporary theories are able to do a reasonable job accounting for existing data. However, ironically, despite the variety and number of theories in the literature, it is not clear that they do well by the criterion of fruitfulness. Arguably, a book like [Eckermann's \(1836/1998\) *Conversations of Goethe*](#) contains more wisdom and could spawn more hypotheses about the nature of creativity than virtually any contemporary psychological overview.

Along these lines, it is also arguable that what is really needed to advance the study of creativity is not a proliferation of more theories, but instead, more, better, and richer data, which could be used to put useful, direction-providing constraints on existing theories. Allied to such datasets, the application of more sophisticated statistical methods – including latent variable models and hierarchical or multi-level regression analyses – would go a long way to documenting and enabling an understanding of the richness of creative phenomena. Importantly, these would also serve to encourage the development of theories that were conceptually equipped to take advantage of added empirical rigor.

In terms of sub-topics within the study of creativity, the potential for the development of theories that go beyond the armchair seems most promising for non-first-person, multivariate aspects of creativity – precisely its aspects that are not amenable to

introspection. These include the details of and variability in the creative process, the neural and other biological bases of creativity, and larger-scale socio-cultural and trans-historical patterns. Empirical study can greatly benefit, or at least most uniquely contribute to our understanding of these aspects of creativity, which would indeed constitute a real advance on the long tradition of armchair speculation.

Conclusion

The variety of current creativity theories has plusses and minuses. On the plus side, there is a pluralistic array of perspectives available. These admirably attempt to understand many aspects of this complex phenomenon, account for current data reasonably well, and have potential for a great deal of integration and cross-connection. On the minus side, many theories have not progressed far beyond earlier speculative claims and have often failed to spark the identification of new phenomena and counterintuitive testable hypotheses. While it is too early to forecast the fate of theories of creativity, and the enterprise of studying creativity more generally, it seems likely that the two will rise or fall together. For any real conceptual progress to occur, existing theories must be continually constrained by more and better data and analyses and generate new constructs for measurement and analysis in their turn.

Time and Creative Problem Solving

Creativity is often defined as a syndrome or complex, with the premise that it is multifaceted. Not surprisingly, several aspects of creative behavior relate to time. This chapter reviews this relationship. It covers several aspects of creativity.

Time has been tied to the cognitive bases of creative thinking. Creative thinking has been defined in associative terms, with the prediction that individuals tend to generate problem solutions in concatenated chains of associations. The first few associations are usually rote, obvious and unoriginal, but the later and more remote associations become increasingly original. Time is relevant to the associative basis of creative thinking because it takes time for an individual to move through obvious ideas to find the remote associates. Predictions about remote ideas being original have been repeatedly confirmed.

One of the most commonly cited models of the creative process was proposed in 1926 by Graham Wallas, who indicated that problem solving consists of the four stages of preparation, incubation, illumination and verification. Incubation implies that some time must elapse before coming up with a creative solution. In the preparation stage, people work on the problem consciously and actively seek for a solution. However, if they cannot arrive at a creative solution and traditional methods do not work, they stop to search for an alternative. It seems that they give up. The incubation stage starts just after preparation. During that time, the individual is not consciously working on the problem - but is working on a preconscious level. The preconscious often succeeds in solving the problem because it encounters fewer constraints than conscious (and logical) efforts. In 1971, J. P. Guilford claimed that Wallas' description of the stages was primarily designed for problems of great importance - problems that demand a long work period. Guilford proposed that Wallas' steps are involved in solving ordinary everyday problems, and they are compressed. Thus, even in your daily problems, you apply these four stages to come up with a creative idea. It is not always obvious to the individual because the stages are compressed.

The need for incubation (and time) was also noted by Sidney Parnes. He distinguished between "make it happen" and "let it happen" strategies for creative problem solving. The former is exemplified by very intentional and systematic tactics, such as working backward (starting with the solution and working back to the initial state) or turning a problem on its head. The latter is exemplified by taking a walk or turning to another task; the assumption is that incubation will occur. This, in turn, assumes that time (for incubation or at least thinking and processing) is useful.

Incubation is often preceded by a state of fixation. This may lead to an impasse as an affective result of a lack of progress. The affect is characterized by negative emotions emerging and feeling stuck. The individual may consciously quit considering the problem. This is the time required for incubation: in other words, the time that is not predated by fixation cannot be regarded as incubation.

Howard Gruber (1993) described how many seemingly instantaneous and sudden insights are protracted and spread out over time. He suggested that insight, or the "Aha! Movement", is *not* a sudden process. Each insight supposedly has a developmental history. According to Gruber, the mastery of creativity requires repeated practice, implying that a great deal of time must be available and invested. For this reason, hard work and repetition are important for creativity. He called this process *constructive repetition* and defined it as a conscious repetition and revision of a concept to establish its best form for a creative product. As an illustration, Beethoven revised his works 20 or 30 times before he decided the final, acceptable form of the piece. This is contrary to the popular conception of insights as sudden. Illumination may seem sudden, but what leads up to it may require time to be invested.

Beeftink et al. (2008) examined the differences between interruptions and breaks (often a matter of choice) on impasses and insights. In the interruption condition, participants are forced to switch tasks at a predetermined moment; in breaks, they can switch

[☆]Change History: May 2019, N Cayirdag updated the text and further readings to this entire article.

This article is an update of M.A. Runco, N. Cayirdag, Time, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 485–488.

tasks when they chose to do so. Both breaks and interruptions contribute to impasses, but interruptions do not contribute to solving more insight problems unlike breaks. Unlike incubation, where the preconscious continues to work on the problem, a break is actual and denotes conscious time away from the task. Taking time away may be required by one of the most general tactics of creative problem solving: changing one's perspective. Changes of perspective can break a mental set or routine, thereby allowing creative insight. Perspectives are often changed literally by finding another viewpoint or way to represent the problem. A new perspective can also be found simply by taking time away from the problem. Every writer knows that one's own work can be difficult to edit if the person is immersed in it. But if you take time away, editorial work is easier. We become more objective and sensitive to details. The same is true in other areas, where time provides perspective.

Studies examining the relationship between time and creativity mostly focus on fluency and originality. Another component of divergent thinking is flexibility. According to Mark Runco, flexibility is more related to coping than other indices of divergent thinking. Flexibility provides the options which are necessary for adaptation. One of the measures of flexibility is category shifts, wherein ideation moves from one category to another. Category shifting and time spending are positively correlated. When people stay in a certain category and generate ideas in it, the process is quicker and generates more ideas during a given time. However, category switching takes longer. The latency between categories is higher than the latency within a category. [Acar and Runco \(2017\)](#) examined the latency between consecutive ideas generated in think-aloud sessions. They found that the average latency was 6.44 s, whereas it was 5 s. higher when people switch from one category to another. They also found that different types of divergent thinking activities require different latency. Generating ideas for figural items takes 2.5 s longer than generating ideas for verbal items.

Timed Tests

Creative potential is often estimated by special tasks or tests. When these tasks or tests are administered, special instructions must be given. Otherwise respondents tend to view the tasks as similar to the academic tests most of us have experienced; and when they do this, creativity becomes a low priority. On academic tests, it is important to find the correct answer, spell it correctly and earn a high grade. When generating original responses to an open-ended task, there may be no correct answer. There may be many appropriate answers, some of which are original and some of which are not, but there is no one correct answer.

To promote the originality of the respondents, grades, conventional answers and time must be deemphasized in the task instructions. Instead of imposing a time limit, examiners should allow the individual to make the pertinent decisions about investing time and effort for him- or herself. By allowing individuals to decide for themselves how much or little time to allocate to the task, the distinctiveness of divergent thinking (and originality) from convergent thinking is maximized. Performance on a test is determined by the respondent's intrinsic motivation, which often facilitates creative thinking. Flexible time limits also allow the individual to find remote associates and perhaps incubate.

There is a common criticism of tests, including tests of creativity, when they are timed. In the natural environment, creative work rarely has a timed component, at least one similar to that used with tests. If we wish to predict real-world creative work, the predictor should require the same tendencies as the criterion behavior. This implies that if creative work in the natural environment is rarely timed, so too should the assessment of creative potential be untimed. According to [Runco \(2016\)](#), even the word "test" is misused in creativity. There is no test that measures creativity. Tests are merely estimates of the potential for real-world creative activity and only show what a particular individual might do. However, because they are called "tests," they are given like other tests with time limits. Thus, there must be constraints in research and educational settings.

Test-like environments may also cause bias against older persons' creativity. According to the peak and decline model, creativity is a characteristic of younger people and peaks in the thirties. Then it declines further as one ages. [Runco and Charles \(1997\)](#) criticized this model because of the implied ignorance of old people's slowness and lack of familiarity with testing. They have lower scores not because they are less creative, but they are slower due to a lack of familiarity with tests compared to younger people. Young people feel more comfortable with tests because they have had a lot of experience during their education. A lack of expertise in testing may cause a cohort effect against the elderly. [Keyes et al. \(2010\)](#) define cohort effect as the specific historical influences on a specific age group. For instance, children born during World War II may have unique similarities not common in any other birth group. The cohort effect is different from the age effect. The age effect is the physiological difference caused by aging, while the cohort effect is social and personal differences caused by common life experiences. A possible cohort effect for the 21st century's young population is test-wiseness.

Developmental Trends and Rates

Time is often used as a categorical independent variable. This is exemplified in longitudinal studies, where various follow-up assessments are conducted after an interval has elapsed. Louis Termán conducted the most famous longitudinal study, although his (gifted) subjects were selected based on IQ and traditional intelligence. Time is also implied by other developmental research, where changes depend on maturation and the passage of time. Some longitudinal studies have found discontinuities and changes that would not be apparent with any other research design. Other studies have found continuities. Consider Robert Albert's longitudinal study of exceptionally gifted boys. His investigation covered more than decades. One of the key findings of a recent follow-up assessment is that certain subjects are "cross overs." By this, Albert meant that subjects change their interest from one domain to another.

The change became apparent only because the longitudinal research design allowed a comparison of career interests and general preferences at several points in time. There are also continuities that can be uncovered only through longitudinal research designs. Mihályi Csikszentmihalyi and Jacob Getzels, for instance, found that art students who invested more time in the preparation of their subject matter were more original - even 18 years later.

The domain specificity of the creativity peak has also been highlighted by Harvey C. Lehman, and later by Dean K. Simonton, in research on exceptional achievement. This line of work suggests that philosophers and social scientists need a longer time to master products than poets and mathematicians. Usually poets and mathematicians peak in their twenties, but social scientists peak later, in their thirties or forties. Development is a lifelong process, and certain discontinuities appear late in life. Some may facilitate creative work. Many older artists are, for example, less concerned with criticism than they were when younger, and this allows them to focus on authentic self-expression and experiment in their work. Martin Lindauer and others have found that many of the most creative artists intentionally changed their style as they got older - often in the seventh or eighth decade. These changes to an "old age style" may have contributed to the artists maintaining a fresh perspective and creative hand. Such changes and perspectives assume that time must pass - the old age style is simply not found in younger individuals. Elapsed time is sometimes not the concern. Time can also be used to calculate other indices of development, such as "rate." Rate is the standardization of occurrence as a function of time. Of relevance here are rates of development and creative productivity that reflect individual differences. There is, for instance, evidence that various facets of thought develop at different rates. J. P. Guilford described in detail different kinds of ideational flexibility and how they mature and fail at different rates. Using Guilford's own terms, the "flexibility of classes" is lost at a different rate than is the "flexibility of transformations."

Kim (2011) examined the development of creativity from a broader perspective. Instead of individual's life-span development, she analyzed the changes in creativity by decades. She analyzed the TTCT scores for the years 1966, 1974, 1984, 1990, 1998 and 2008. Her findings showed that creativity has declined across recent years as measured by TTCT. This implies a reverse "Flynn effect", which refers to increments in IQ in younger generations.

Expertise as Time Invested

Raymond Cattell and John Horn suggested two kind of intelligence: fluid and crystallized. Fluid intelligence is the ability to solve novel problems with a little to no previous knowledge. For instance, someone suddenly realizes that a hanger can be used as a back scratcher. Crystallized intelligence, by contrast, is remembering and using information acquired by previous experience and education. For instance, solving a new math problem requires previous knowledge and expertise in math. In Ceci and Liker's (1986) classic study, researchers asked the same problem to two groups of men: experts and non-experts in the field. There was no significant IQ difference between the groups. Results showed that the experts used more sophisticated and complex strategies to solve the problem than the non-experts. Experts solutions are richer and more organized, and this group is more aware of what they do not know.

Some domains require years to develop expertise. Various investigators have suggested that 10 years (or 10,000 hours) need to be invested in a domain for expertise to develop. To the degree that expertise is necessary for creative work, this may, indeed, be a requisite investment. In some areas, expertise may be easier to obtain and requires less of a temporal investment (domains that depend the least on familiarity with a body of information). What may be surprising is that expertise may inhibit creative insight. Experts sometimes make assumptions that preclude original thinking. They have invested so much into their areas of expertise that they are resistant to alternatives.

Dean Simonton described other requisites for high-level achievement. He pointed to three tendencies of eminent persons: they start their careers early, they are productive and they live a long time. Time is involved in each of these. Time is also implied by economic and investment theories of creativity that use the parallel idea that creative persons tend to invest a great deal in their work. Investments may be temporal. This may sound like another way of saying that expertise takes time to develop, but here it is more that the person concentrates frequently on the task at hand or field of choice. It is possible that investment can work against creative success. In this sense, the psycho-economic theories of creativity support the idea that expertise can sometimes inhibit original thinking. Theoretically, an individual who has invested a great deal in one idea or mode of thinking would experience a "depreciation" of his or her knowledge if the new thought supplants the old; in fact, this may lead to resistance of the new lines of thought.

Subjectivity of Time

The research above that notes the inhibitive effects of time constraints should not be taken to suggest that everyone would be disturbed by deadlines. According to cognitive evaluation theory, the influence of limits is only likely when perceived as pressure by the person. This is the subjectivity of time. Along the same lines, time may be conceived as occurring in routines and schedules, thereby easily perceived as boring or repetitive. As such, they may make it difficult to maintain one's creative efforts.

Creative individuals may have certain cognitive capacities and abilities to produce creative ideas, but they must also be interested in using those capacities and abilities while working. This is described as "intrinsic motivation." If intrinsically motivated, the individual will invest time and effort into a task, problem or domain. Importantly, an event may increase or decrease intrinsic

motivation depending on its meaning for the recipient. Recall that, according to cognitive evaluation theory, if an event is perceived as a pressure to reach a goal (as controlling), intrinsic motivation is undermined. On the other hand, if an event is perceived as an internal locus of causality for behavior (informational rather than controlling), it enhances intrinsic motivation. Therefore, perception of time limits counts.

Koestner et al. (1984) examined the influences of limits on children's creativity and intrinsic motivation. In a creative activity, children with no-limit or an informational limit spent more free choice time, an indication of high intrinsic motivation, than the children who had controlling limits. When it comes to products, the no-limit condition was superior to controlling condition in terms of creativity ratings. Higher technical quality of the products was evident in the informational limit condition than the controlling condition.

If routines are imposed by others, they tend to hinder creativity because they function as a kind of pressure. Yet, according to Mihályi Csikszentmihalyi, not all routines harm creativity. In fact, some persons work best under pressure. Moreover, time is a function of subjective interpretation, and different people will interpret time periods variously. The subjectivity of time and the relationship between that interpretive tendency and creativity is implied by research on "flow." Flow is characterized by a loss of self and a loss of the awareness of time passing.

The subjectivity of time and a second connection to creativity is suggested by the ability of certain creative persons to look beyond the present. This tendency is epitomized in the "future problem solving" educational program and the "proactive creative work" of some creative persons. Proactive creative efforts may allow us to avoid problems, or solve them when they are minor, rather than solving them when they are no longer deemed unmanageable. One part of the subjectivity of time can be explained by "cognitive style." Impulsivity and reflective cognitive styles have been isolated, and they differ in terms of how much time is required or used by the individual. Perhaps one individual uses a great deal of time because he or she is not really aware of its passing. Indeed, this is one of the basic premises of the concept of flow. To the extent that creative insights are often protracted, impulsivity might decrease the likelihood of creative work.

Attribution of Creativity and Time in Interpersonal Processes

Time is required for some of the social, interpersonal processes that contribute to creative work or are involved in our judgment of it. Many researchers have argued that the attribution of creative ability is most accurate only after a long period has elapsed, ostensibly giving the judges a better perspective. The need for a long-term perspective is evidenced by the changes that sometimes occur in reputations. Rembrandt, for example, was not the most famous artist of his time, but he is now one of the best known of his era. The work of Gregor Mendel was largely overlooked for 50 years.

An issue arises when eminence is defined in terms of social attribution. This brings into question the idea of a creative genius being ahead of his or her time. If creative geniuses are ahead of their time, their genius might not be recognized. Records might not be kept of his or her work and no attention would be given to it. The assumption is that the reputation of creative exceptionality emerges from the social and cultural context. This may occur in two ways. The product may not receive much recognition during the creator's lifetime; or the exceptionality may be recognized during the genius' lifetime but forgotten after his or her death. As a result, necessary resources might not be allocated to the individual because of a lack of appreciation. In this light, the creativity might never develop to the level of exceptional achievement. A second interpersonal issue involves the possibility that immediate temporal constraints may undermine creative work. This was implied earlier in the discussion of task instructions for the assessments of creative potential. It was further intimated by the attributional process that some apply to judgments of creative performance. It may be explained by referring back to the economic theory of creativity, because time is defined as a resource. Time can be invested in training or work. This becomes an interpersonal dynamic when other persons (e.g., parents, teachers or supervisors) decide how much time should be invested.

Culture

Clearly, cultural norms and expectations shape an individual's creativity. Novelty or originality is one of the important criteria. What is original in one culture may not be original in another. People may not think of possible solutions to a problem because they are taboo within their present culture. According to Lubart (1999) Western creativity focuses on innovation, or products. Adults may not consider humor or play as contributions to creative work: work is supposed to be serious rather than fun. Thus, there is often pressure to work quickly and to be productive. It may not be easy to tolerate incubation and appreciate the value of "let it happen" tactics. Time is a valuable commodity and incubation may be a waste of time for some.

On the other hand, Lubart defines Eastern perspectives of creativity with personal fulfillment and the expression of inner essence. In Eastern societies, creativity needs more time, because it is a journey of exploration to the true nature of the self. As opposed to the negative view toward tradition of Western culture, Eastern views of creativity acknowledge tradition. Time is not linear from the Eastern perspective; it is something expected and valuable to have ties with the past. Creativity is an ongoing process of reinterpreting traditions and the nature of the universe.

Another difference between Eastern and Western cultures is the influence of formal education on creativity. In his historiometric studies, Simonton analyzed the differences between Eastern and Western cultures and found that the level of formal education

positively correlates with creativity in Eastern societies. However, spending more time in formal educational institutes may be detrimental in the West where the relationship between the level of formal education and creativity is an inverted U curve.

Conclusion

Time is thus relevant to several cognitive and metacognitive processes that might be involved in some creative thinking. It is related to incubation and necessary for the remote associates that tend to provide original ideas. Time can be used strategically in “let it happen” tactics, and it may be indicative of the investments and intrinsic motivations of creative persons. It should be explicitly deemphasized when using tests of creative potential. The cultural basis of time should be acknowledged, even as specifically associated with creative work, as should the value of time as a resource in most organizational and educational settings.

Time is used in areas of creativity research in addition to that reviewed in the present article. Gudmund Smith, for example, varies the exposure time in his Creative Functioning tests, while Norbert Jaušovec examines heart rates as related to stages in the creative process. The relevance of time is widely recognized and even more varied than the present overview might suggest. Very likely, most or even all of the ways that time influences creative behavior should be qualified. After all, virtually all other influences on creativity show optimal levels. Divergent thinking, for example, often supports creative problem solving, but only up to a point. You can be too divergent (and never bring an idea down to earth to make it useful). You can also be too independent, too conventional and too intrinsically motivated. Again, it may be that all influences on creativity are most effective at an optimal rather than extreme level. Time, then, may also have optima. Just to name one example, incubation may be a good thing for creative thinking, but perhaps only for a period of time and certainly not *ad infinitum*. The same optimization may apply to all temporal influences and correlates.

Introduction

The term tolerance for ambiguity is found in the creativity literature, expressed perhaps as tolerance of ambiguity, tolerance toward ambiguity, tolerance toward ambiguity, ambiguity tolerance, or even tolerance of uncertainty, as a commonly cited trait of the creative personality, both young and old. For example, while drawing attention to the paradoxical nature or antinomies of the creative person, [Runco \(2007, p. 314\)](#), asserted that:

The creative personality can be described with some combination of the following ...: autonomy, flexibility, preference for complexity, openness to experience, sensitivity, playfulness, tolerance of ambiguity, risk taking or risk tolerance, intrinsic motivation, psychological androgyny, self-efficacy, wide interests and curiosity.

In this context, tolerance for ambiguity is generally defined to be a propensity or proclivity to perceive ambiguous situations as desirable ([Budner, 1962](#)). In taxonomies of recurrent attitudes and traits of creative people, tolerance for ambiguity tends to be described as a tolerance of disorder and an attraction to complexity, and it is set alongside other traits such as attraction to the numinous, the mysterious, the asymmetrical and the incongruous.

Historical Development

Originally, tolerance for ambiguity was proposed as the converse of intolerance of ambiguity, a construct that surfaced during research on the authoritarian personality. The construct of the authoritarian personality is clearly a highly relevant and important issue in prejudice and cross-cultural studies, and grew out of work by both Erich Fromm in the 1930s on the authoritarian character, and Abraham Maslow in 1943 on the authoritarian personality. Then, from 1943 until 1950, Theodor Adorno (well known for his contributions to the Frankfurt School), Else Frenkel-Brunswick, Daniel Levinson, and Nevitt Sanford conducted an extensive, long-term, anti-fascist research project, examining the traits of the authoritarian personality and their relationship to the potentially fascistic individual. Their study involved the construction of a series of instruments to measure prejudice, and included an "A-S [for anti-Semitism] Scale", a "PEC [for political-economic conservatism] Scale", and a ranking scale called the "F [for fascist, or for pre-fascist, or for potentially fascist] Scale", which later morphed into the "E [for ethnocentricity] Scale". In 1950, the findings from their search for the fascist personality were published in a monumental and now classic 990-page tome, entitled *The authoritarian personality* ([Adorno et al., 1950](#)).

For part of this research project on the authoritarian personality, Frenkel-Brunswick specifically examined attitudes toward ethnic prejudice, and from the findings published three seminal papers on intolerance for ambiguity ([1948, 1949, 1951](#)). [Frenkel-Brunswick \(1948\)](#) comprised an abstract of her study, reporting that the intolerance of ambiguity variable was a general personality variable foundational for social orientation (p. 268):

The prejudiced are significantly more often given to dichotomous conceptions of the sex-roles, of the parent-child relationship, and of interpersonal relationships in general. They are less permissive and lean toward rigid categorisation of cultural norms. Power-weakness, cleanliness-dirtiness, morality-immorality, conformance-divergence are the dimensions through which people are seen. ... There is sensitivity against qualified as contrasted with unqualified statements and against perceptual ambiguity; a disinclination to think in terms of probability; a comparative inability to abandon mental sets in intellectual tasks, such as solving mathematical problems, after they have lost their appropriateness. (p. 268)

Frenkel-Brunswick carefully laid out the evidence and argument in support of her model of “one of the basic variables in both the emotional and the cognitive orientation of a person toward life and what she [speaking of herself] has suggested be labeled *tolerance* versus *intolerance of ambiguity*” (Frenkel-Brunswick, 1949, p. 113, italics in original).

Her study involved the construction of a series of instruments to measure prejudice and for the assessment of related factors. Initial data were collected from 1,500 American school children aged 11–16 years old; 120 of these children, who represented to Frenkel-Brunswick the extremes of either prejudice or freedom from prejudice, participated in individual interviews and projective tests, and their parents were also interviewed; in addition, about 40 of these children were subjected to further tests of perception and memory. She found that the denial, avoidance, or elimination of ambiguities (often expressed as a distortion of reality) could be understood in terms of a rigid adherence to a norm: “Assumptions once made, no matter how faulty and out of keeping with reality because of neglect of relevant aspects, are repeated over and over again and not corrected in the face of new evidence” (p. 119). She concluded that an intolerance of cognitive ambiguity and a denial of emotional ambivalence were simply different aspects of what appeared to be a fairly coherent characteristic.

Frenkel-Brunswick (1949, p. 141) argued, finally, that “The struggle between these two orientations is basic to our civilization, its individual members display these two patterns in varying proportions and changing configurations.” In the full report on the authoritarian personality Frenkel-Brunswick (Adorno et al., 1950) concluded that:

It is perhaps mainly the readiness to include, accept, and even love differences and diversities, as contrasted with the need to set off clear demarcation lines and to ascertain superiorities and inferiorities, which remains as the most basic distinguishing criterion of the two opposite patterns. (pp. 485–486)

In any case, what clearly remains is a supposedly linear ethnocentricity variable, and a scale that purports to measure this variable. For this variable, ethnic prejudice is set against its purported opposite, which might be termed ethnic unprejudice, and for this variable Frenkel-Brunswick’s (1948, 1949) construct of Intolerance of Ambiguity appears to play a very important if not a central role.

Creativity and Tolerance for Ambiguity

After the report on the authoritarian personality researchers in psychology were quick to apply its findings and methods to areas other than ethnic prejudice. For example, O’Connor (1952) explored the relationship between ethnocentrism, intolerance of ambiguity, and abstract reasoning ability, and found that intolerance of ambiguity was not particularly correlated, one way or another, with abstract, syllogistic reasoning ability.

Then, in an essay on creativity and culture, Stein (1953, p. 312) brought the concept of tolerance for ambiguity into the creativity literature:

The creative person has a lower threshold, or greater sensitivity, for the gaps or the lack of closure that exist in the environment. The sensitivity to these gaps in any one case may stem largely from forces in the environment or from forces in the individual. Associated with this sensitivity is the creative individual’s capacity to *tolerate ambiguity*. By ‘capacity to tolerate ambiguity’ I mean that the individual is capable of existing amidst a state of affairs in which he [or she] does not comprehend all that is going on, but he [or she] continues to effect resolution despite the present lack of homeostasis.

Since then, the term tolerance for ambiguity was included in lists of prerequisites for the creative personality by some writers, for example Carl Rogers. The research support for this inclusion, however, is not so unequivocal. In an early and representative study on characteristics of the creative individual, Guilford et al. (1957), considered non-aptitude traits possibly related to creative performance in the visual arts. Three primary traits of interests that might contribute to different kinds of creative thinking emerged: reflective thinking, rigorous thinking, and autistic thinking (*sic*). They also found a pair of primary interests in aesthetic activities, seen as aesthetic appreciation and as aesthetic expression. Then, using self-inventory scores, a factor analysis found indications of some of the expected variables. Two factors identified were an interest or liking for convergent thinking, and an interest or liking for divergent thinking. A third factor was found but remained elusive and only vaguely identified, although it did appear to be related to an interest in aesthetic activities. A fourth factor was identified, tentatively, as tolerance for ambiguity, which was interpreted to mean a willingness to accept some uncertainty in drawing conclusions and in making decisions, along with a tendency to avoid thinking in rigid terms.

Note that the language used in reporting the findings of the research conducted by Guilford et al. (1957) was vague, and only suggested that tolerance for ambiguity might be a trait of the creative personality. Nevertheless, tolerance for ambiguity is now often referred to as the *sine qua non* of creative achievement, and if a supporting reference is cited (and all too often one is not cited) it tends to be either to Csikszentmihalyi (with a date, and hence with no actual reference), or to Vernon who edited a collection of articles on creativity.

Other studies on the relationship between tolerance of ambiguity and creativity naturally focused on adult creative and intellectual abilities and behaviors:

- From his research involving industrial research chemists, Stein (1963) found that the creative person ‘has a personality structure which may be characterized as an open system with minimal entropy and which is unencumbered by excessive homeostatic

mechanisms' (p. 225), that is, the creative person has a more positive self-image and is able to tolerate the ambiguity that is involved in long-term research.

- [Barron \(1968\)](#) noted that the creative personality was tolerant of other people, although many counter examples may readily be found in the literature.
- In summarizing his research on an eclectic and purposive sample of creative writers, scientists, conservative businessmen, bohemians, and engineering students, [MacKinnon \(1978\)](#) mentioned their general tolerance of other people or tolerance toward other people.
- [Comadena \(1984\)](#) found that ideational fluency during brainstorming sessions was associated with a tolerance of ambiguity.
- [Tegano \(1990\)](#) discovered a positive correlation between creativity and both playfulness and tolerance of ambiguity.
- [Furnham and Avison \(1997\)](#) found that individuals with a preference for surrealistic paintings tended to have a high tolerance of ambiguity, which they saw as an indication of a relationship between tolerance of ambiguity and aesthetic preferences.

Tolerance for Ambiguity and the Creative or Gifted Child

In definitions and models of giftedness, creativity is usually understood to be either a necessary component of giftedness or one of the possible ability domains of giftedness. Lists of characteristics of gifted school students, include components that are similar to lists of characteristics of creative adults.

Research regarding tolerance for ambiguity in the field of creativity and education (that is, the education of the creative child and of the gifted child) appears to have been sparse.

- [Smock's \(1955\)](#) study on complex decision-making and response preservation involved child participants, and found some evidence that anxiety is one of the correlates of tolerance of ambiguity. This study also suggested that the tolerance of ambiguity variable is non-linear, that is, individuals with greater tolerance for ambiguity and individuals with less tolerance for ambiguity may behave in extreme ways at opposite ends of the spectrum.
- [Stoycheva](#) found surprisingly that behaviors related to both tolerance for ambiguity and intolerance for ambiguity were valued by adolescents and positively perceived and encouraged by teachers and parents ([Stoycheva, 2011](#)). She rationalized this equivocal finding by arguing that while following norms, seeking certainty, and avoiding risks may be desirable personal outcomes, so too are experimenting, seeking challenges, and exploring new and uncertain situations.

Conclusion

Since the construct intolerance versus tolerance of ambiguity was first proposed by Frenkel-Brunswik in 1948, there has been sparse research conducted on its applications, in particular with respect to the study of ethnic and national cultures, of marketing, and of organisations, including business management and the armed forces. During this time, the construct has evolved from a negative conception, that is, intolerance of ambiguity, to a positive conception, that is, ambiguity tolerance in its various guises.

For excellent reviews of measures of tolerance for ambiguity, see, in particular, [Furnham's \(1994\)](#) factor analytical study of four tolerance of ambiguity questionnaires, and the extensive review by [Furnham and Marks \(2013\)](#). Here it is interesting to note that Furnham and his colleagues drew attention to a lack of sophistication in the literature about tolerance for ambiguity, and that there is no clear operational definition of the concept and its related forms. In fact, [Adorno et al. \(1950, p. 1\)](#) pre-empted the vagueness of such findings by pointing out clear differences in how the concepts of intolerance for ambiguity and of tolerance for ambiguity are understood:

Individuals who show extreme susceptibility to fascist propaganda have a great deal in common. (They exhibit numerous characteristics that go together to form a *syndrome* although typical variations within this major pattern can be distinguished.) Individuals who are extreme in the opposite direction are much more diverse.

That is, the evidence in support of tolerance of ambiguity as a trait of the adult creative personality is not strong and at best it is equivocal. And the evidence in support of tolerance of ambiguity as a personality trait of the creative child or adolescent (and of the gifted child or adolescent) is weaker still. There may be good and compelling theoretical reasons, and, intuitively, plenty of good common sense, for wanting to make these connections. However, a better understanding of the construct is needed, along with better ways to measure it.

Introduction

The relationship between travel and creativity has always been very solid. Traveling inspired some of the most remarkable pieces of art and literature, and Gauguin, Picasso, El Greco, Pollock, O’Keeffe, Homer, Goethe, Conrad, Steinbeck, or Hemingway would probably not have produced some of their masterpieces if traveling had not been involved. Likewise, great photographs, films, and many different creative expressions exist thanks to the evocative power of traveling and the contact with the different countries and cultures it conveys.

Accordingly, traveling, and hence tourism, can constitute an important source of creativity but not exclusively reserved for great geniuses such as the examples mentioned earlier. On the contrary, the option to increase creativity through tourism is potentially open to all people who decide to embark on a trip and leave home, ready for a change.

On the other side of the ocean, tourism professionals will be trying to draw on their creative potential and ideas to do their job: to attract more and more tourists and exceed their expectations. However, before proceeding any further, let us clarify what is going to be understood by tourism in these pages.

There are different definitions of tourism that circumscribe it to personal reasons such as recreation, relaxation, and pleasure while other broader definitions extend it to business and professional purposes. In either case, the common denominator is that it entails the movement of people to countries or places outside their usual environment (World Tourism Organization). So here lies some of the keys for creative thinking: this movement brings along change and change, in turn, can facilitate the adoption of new perspectives that can help to ignite the creative process. However, this is not always the case, and while for some people traveling and tourism are stimulating activities that can trigger their creative potential, for others it is a tedious, ordinary, and sometimes stressful part of their lives. In short, not all tourism forms will lead to creativity.

Here the term “tourism” will be used in its broadest sense; namely, the movement of people to other places different from their usual residence, using the commercial and hospitality services provided by the industry (transportation, accommodation, catering, entertainment, activities, and so on). Likewise, in the text we will not make a priori distinction between tourists, travelers, or visitors because although the terms may have many different implications, the significant issue here is the relationship between individuals and creativity without preconceived assumptions.

With the aim of reflecting the connections between tourism and creativity, there have been two basic approaches that summarize the two reasons for the trip: one is the more widely studied view which focuses on the idea that by using creativity individuals,

companies, or destinations can devise new proposals and initiatives aimed at attracting more tourists. At first glance, this could be considered just a greedy marketing strategy. However, creativity can encourage innovation and individual skills as well. This approach is being researched within the field of creative tourism.

The other view, with a significantly lesser number of studies, delves into the idea that tourism, under certain conditions, can constitute a valuable resource to improve people's creativity. Both perspectives will be taken into account. The first part will deal with creative tourism and all the aspects associated with it and the second with the effects that tourism produces on travelers from a creative point of view.

Creative Tourism

The concept emerged in the 1990s with the work of [Pearce and Butler \(1993\)](#) who considered creative tourism as a potential type of tourism. Then, the EUROTEx Project, a cultural tourism development project funded by the European Union (1996–99) ([Richards, 1998](#)), and the first Creative Industries Mapping Documents (1998) opened new ground for the appearance of different perspectives on the subject. In addition to Richard's contributions, especially relevant and influential were the works by [Landry \(2000\)](#) with his creative cities approach, and [Florida \(2002\)](#) who highlighted the emergence of the creative consumer, coined the concept of the creative class, and established the indexes of creativity. Creative cities are characterized by using creativity as a strategic factor for urban development plans and developing the artistic, cultural, and social city life. They constitute a powerful attraction for the creative class, composed of creative people who stimulate innovation and work in the creative sector.

Scholars have offered different definitions of creative tourism that share some common elements, emphasized by [Richards \(2011, p. 1237\)](#): "participative, 'authentic' experiences that allow tourists to develop their creative potential and skills through contact with local people and their culture. This formulation suggests a shift towards active rather than passive forms of consumption, and an emphasis on 'living' or 'intangible' culture rather than static, tangible cultural heritage. The essence of creative tourism seems to lie in activities and experiences related to self-realization and self-expression whereby tourists become co-performers and co-creators as they develop their creative skills."

Creative Tourism and Cultural Tourism

From its very origins, creative tourism has been considered a natural sequel to cultural tourism, which in the last years has been suffering a process of overcrowding, homogenization, imitation, and lack of uniqueness that requires corrective action.

Features such as overdevelopment, undermined value reduced returns, and lack of investments have been associated with the reality of cultural tourism in recent times. As a result, other sorts of more innovative, singular forms of tourism, more difficult to duplicate, have been developed, giving rise to creative tourism initiatives, based on more interactive and authentic experiences, such as arts, crafts, and cookery workshops. It is important to note that creative tourism, though initially an evolution of cultural tourism, has managed to gain its position and become a typology on its own.

One of its main points is the development of the aspects of culture (rituals, social practices, festive events, and so on), offering a new wide range of alternatives for destinations, allowing more local cultural symbols to be shown, shared, and hence, perpetuated. Traditional music and dancing, local food technologies, ethnographic practices, or traditional crafts are examples of the type of experiences that can be enjoyed and shared by tourists and locals. This emphasis on intangible culture resources allows for fresh approaches and opportunities in those places lacking a great monumental heritage. Innovation, creativity, and entrepreneurship can complement or make up for other tangible cultural attractions, generating other products and experiences that can attract more visitors and stimulate both the local economy and the cultural idiosyncrasy of the area.

It is also important to emphasize the need to avoid the standardization of tourism products and concentrate on the individualization of tourism experiences. Creative tourism can be a way of approaching cultural tourism in a different way, paying attention to nontraditional uses of the cultural potential of destinations.

Creativity and Experience: Interaction and Authenticity

Several studies tried to identify the different components of tourism experience and its relationship with creativity ([Hung et al., 2016](#); [Tan et al., 2013](#)). To make a tourist experience affect creative thinking and behavior, it is necessary to fully immerse tourists in some sort of interactive tourism experiences, such as the ones mentioned earlier, that can take place in different dimensions of tourism: entertainment, educational, esthetic, escapist, relaxation, involvement, and pleasure.

In addition to being interactive, experiences require authenticity: tourists need to perceive that every experience they are living is authentic. However, tourism providers have to be especially careful about creating new experiential spaces as they can convey a loss of authenticity.

The genuine preservation of culture and traditions in different populations is a powerful attraction for some tourists who would like to share idiosyncratic practices with the locals/residents in their wish to experience ancestral rites and traditions. This interest is especially important as it can help to revitalize those areas.

A highly significant aspect of creative tourist experiences is that they leave deep impressions on participants and have a profound influence on memories, level of satisfaction, and behavioral intentions (revisit intention and positive word of mouth). Those who

have pleasant memories and are satisfied are more likely to revisit and recommend the destination. This situation is more likely to happen when the process implies that tourists and locals are involved in the creation of the tourism product (cocreation). As a result, the generated creative experiences spark the desire to return to the destination, emphasizing the vital link between creative tourism and visitor loyalty.

Accordingly, to encourage memorability and loyalty, it is especially relevant to provide a high-quality experience, in which visitors are actively involved, participating in the cocreation of stimulating, interesting, and affordable activities (Suhartanto et al., 2019).

The Human Factor

The Tourists: Consumers Versus “Prosumers”

Creative tourists have quite a defined profile that makes them different from conventional tourists. After all, they are in search of experiences in accordance with their personality and their way to view life. They tend to be proactive and friendly, open to diversity, and willing to learn and share but they also avoid mass tourism and value sustainability and social and economic responsibility.

Accordingly, in creative tourism, tourists play a highly participative role, so they are considered in a different way. They possess specific features that make them coproducers of experiences becoming “prosumers” rather than consumers.

A robust link is established between consumers and producers, and the final experience will be the result of their mutual involvement in the activity. Knowledge transfer, participation, and practice are necessary ingredients to carry out the devised tasks. In this view, the collaboration of the tourist is essential. Scholars have analyzed in depth quite a few examples of this type of exchange, ranging from gastronomy, tango, flamenco, or hip-hop tourism to tourist performances in collaborative guided tours. In all of them, the interactions of tourists and providers are essential to generate the final product or activity.

It is important to note that once tourists have the opportunity to be involved in this type of proposals, they frequently lose their interest in conventional ways of traveling and seek to experiment with similar activities.

Creativity in Tourism Providers

Creativity is also considered an essential ingredient for tourism providers with the aim of their getting a better development of the sites, attractions, or destinations.

Considering that cocreation is a crucial element for a creative tourism experience, some researchers have emphasized the fundamental role of tourism providers, who should work on their creative skills consciously. This process is especially important when it is necessary to exploit the intangible value of a resource. A cocreative perspective requires the active participation of tourists with the aim of making an unforgettable and unique experience, so tourism providers should be able to “create” powerful engaging interactive approaches that call for the intimate, personal, and emotional side of tourists.

For this reason, tourism providers should get adequate training to enhance their creative skills and be able to devise cocreative approaches to add additional value to the specific site. Fostering their creativity and getting specific training about how the tourist resources can be exploited through cocreative activities can help promote new business opportunities and get a higher level of satisfaction in tourists through more memorable experiences.

Likewise, in order to facilitate creativity in tourism and hospitality employees, some studies have been developed inside organizations to propose new models based on shared knowledge within an adequate work environment and positive atmosphere (Tsai et al., 2015).

Additionally, providers of creative tourism should be able to stimulate, encourage, and promote those features associated with creative development such as tourist involvement and interactivity with the local culture to learn something new and obtain a unique experience. At the same time, they should try to fulfill tourists’ needs for escapism, show consistent respect, and make visitors feel safe and secure to get the necessary peace of mind to be relaxed.

Some companies and business consultants are devoted to the training of future creative entrepreneurs and tourism professionals, organizing specific courses adapted from innovative methodologies and resources, such as Serious Play, Design Thinking, Business model Canvas, Lean Startup, the Competence wheel, or Binnakle, to name just a few. This sort of training that aims to awaken and foster the combination of creativity and entrepreneurship is especially crucial in the case of creative tourism, as most potential promoters are also small investors with limited business experience.

Creativity Occupations: The Creative Class

Together with tourism promoters and tourists, there is a third group of protagonists who form the human creative tourism triangle chart. These individuals are members of the denominated “creative class” (Florida, 2002), composed of people working in the creative sector. This group feels deeply attracted to places that have a creative atmosphere, contributing, thanks to their presence, to the configuration of even more creative space and image.

The synergies generated by this human force, together with other factors that will be analyzed in what follows, will allow the link between tourism and creativity to form a powerful symbiosis with highly interesting consequences for tourists, promoters, and residents.

Products

The most significant elements that are going to channel new creative thinking and development opportunities are the different activities, resources, spaces, services, and events that the tourism industry will exploit to devise and offer a new product.

When we talk about creative tourism products it is essential to take into account that to be considered creative and effective, the product has to be more than “new.” It has to include the different features we mentioned earlier, namely, learning, emotional involvement, interaction, and cocreation, provided in an authentic atmosphere. The common aim is that the resulting activity becomes a memorable experience for the tourist.

Creative tourism products can entail two different components: tangible resources, which usually involve the implication of manual activities (cooking, handicrafts), versus intangible resources that include the living expressions and traditions inherited from ancestors (rituals, social practices, festive events, and so on) and require the use of different strategies, such as the constructivist ones. These strategies are grounded on the participants’ contextualized active involvement, so knowledge is acquired through personal experiences.

Accordingly, creative tourism proposals will often depend on the ability of a destination to boost added value to their cultural heritage and natural resources to attract visitors. In the case of manual activities, the crafts sector is especially relevant as creativity is required not only to overcome the different problems and limited resources that artists have to face but to design and create products that can be attractive for potential customers. Together with artistic colonies, crafts, and gastronomy, other examples of experiences include perfume making, porcelain painting, dancing, textile art, ceramic production, and so on. These creative skills can constitute a source of tourism development, and local communities can transfer their skills in crafts and design to visitors. Currently, there are lots of different creative tourist products and routes everywhere in the world.

Valuable assets for the creation, promotion, and launching of new products are the essential existing synergies between tourism and the so-called creative industries (advertising, architecture, art, crafts, design, fashion, film, music, performing arts, publishing, software, toys and games, TV and radio, and video games; [DCMS, 1998](#)). Integrating the “products” resulting from the creative industries can enrich tourism experiences, generate tourism demand, develop new creative tourism products, and enhance place quality and attractiveness ([OECD, 2014](#)).

All types of tourism initiatives can develop new creative options that can cause a fundamental change in destinations, even having the power to transform them. Recent examples are experiences based on films, series, music, or gastronomy that share the common aim of offering more interactive approaches.

Together with products, events are highly important resources for creative development everywhere, serving to develop economic and cultural linkages between locations and communities. They offer an excellent opportunity to concentrate on different cooperating creative networks and all the elements present in the tourism industry, providing a perfect connection between creativity and tourism. Sometimes, specific events and festivals of different orientation all over the world can become a symbol around which creativity spans and develops around.

An interesting aspect of events for creative tourism is that the attendees are usually a combination of residents and tourists, so events constitute a perfect context for the interaction between them. From the point of view of creativity, the new trends in event organization are characterized by their innovative and participative orientation. The primary objective is that the staging of the event and the engaging, high involvement activities, leave a memorable and transformational experience for visitors and tourists alike. Events seek change and change triggers creativity.

Events are perfect examples of where to see the overwhelming and stimulating echo of creativity in every part of its development and final representation, for both planners and attendees. Tourists immersed in these integrating and interactive activities will share a very favorable context for creative development.

Locations

Every place has the potential to constitute a creative attraction pole for visitors. Locations have a natural, cultural, and monumental heritage that together with their human capital can join forces to project new specific innovative products, events, and experiences that shape an appealing destination irradiating a unique and special atmosphere.

Creative tourism opens the door to alternative public spaces, different from the most visited landmarks, contributing to revitalizing other parts of the destinations and control overcrowding in emblematic spots.

Cities

With the beginning of the 21st century, several scholars highlighted the strong relationship between creativity and urban contexts for many different reasons ([Laundry, 2000](#); [Florida, 2002](#)). On the one hand, creativity was considered to play a crucial role both for creative industries and society and on the other, it was highlighted that creativity could be fostered, becoming, in this way, an essential ingredient to solve urban problems.

The reason behind this link between creativity and cities lies in different features that characterized urban areas: their dynamic and changeable nature, their significant role for innovation, and their diversity, all factors that are frequently related to creativity. For

some tourists, creativity is more easily perceived in places with a multicultural, diverse, and cosmopolitan atmosphere. Likewise, urban, cosmopolitan areas have also been considered essential poles of attraction for the so-called creative class.

All types of cities can be creative in different areas. Since 2004, there is an initiative promoted by UNESCO (UNESCO's Creative Cities Network) to agglutinate a wide range of cities that are primarily characterized by a distinctive creative profile in various fields: literature, design, crafts and folk art, film, music, media arts, and gastronomy. They claim that they offer great opportunities for cities to draw on collaborative projects to make the most of their creative assets. At present, there are more than 180 creative cities all over the world, classified under the categories mentioned earlier.

Creative tourism offers new possibilities by recovering different areas and resources, making the implied destinations more attractive. Sometimes creative people and clusters settle in neglected parts of cities, changing their physiognomy and atmosphere to become more attractive for new residents and visitors. The fact of being part of the UNESCO network of creative cities can also be a powerful stimulus for the cooperative work of different tourism managers.

Rural Environment

Especially interesting is the view that creative tourism in rural areas is more than a set of new tourist products: there is a revival of the community's social dynamics, traditions, and cultural values. In this scenario, creative tourism can contribute to the development of community-based tourism in two ways: first, it can help to foster local communities' self-confidence and empowerment, and second, it can improve the living conditions and lifestyle of autochthonous populations. It is especially significant that creative tourism can contribute to increasing enthusiasm for intercultural exchange.

The authenticity of rural environments can also attract creative initiatives, such as the settlement of artist colonies that are often transformed into crafts and design centers that become, in turn, an attraction for consumers of creative tourism. In this way, creative tourism promotes rural innovation of spaces and fosters creative job positions.

Rural environments often constitute a sort of Arcadia for people from the creative sector and lifestyle entrepreneurs who have decided to leave the city. In this context, the proliferation of creative clusters has been commonplace. The potential of the rural environment for creative development is such that a wide range of creative tourism initiatives can be found here. Examples such as arts/crafts festivals, master classes, textile crafts, folk art, or workshops are typical in rural areas all over the world.

In addition to the role of human-made creative products, rural areas may include natural resources that serve as a basis for creative proposals, customarily based on effective staging and narration. Sometimes nature itself (unique natural landscapes, wild animals) is marketed as a tourist product, and tourists become the agents of a "dramatized" performance that they could not observe by themselves without the mediation of a tourist product.

However, it is important to note that sometimes, both in the case of cities and rural areas, adversity can trigger creative behavior and strategies. There are different examples of neglected areas of cities that have been drastically transformed due to the colonization of degraded neighborhoods by artists or industrial cities that thanks to creative initiatives have entirely changed their image and projection.

Impact on Destinations

The fact that tourists become proactive agents of tourism experiences contributes to a change in the pace of life and atmosphere of destinations, becoming part of the bustling and stimulating rhythm of cities or the invigorating power of natural and rural environments. They transcend their role of visitors to become part of the community. They absorb knowledge and experiences, but they also leave their imprints behind.

These tourists, very frequently, do not feel like tourists and do not like to be identified as such. They want to be integrated into the destination, sharing as many aspects of the locals' lifestyle as possible and experiencing a sense of authentic immersion. It has been highlighted that this type of "nontourist" prefers to consider that their trips are more an extension of their everyday life than a contrast to it. They are happy to live together with the locals, interacting with them and sharing their daily lives.

This formula is becoming so popular that many new entrepreneurs are creating companies based on the interaction between tourists and locals, with meals in residents' homes, city walks, countryside exploration, and so on. In any case, the features and profile of tourists interested in this kind of interactive, cocreative activities will limit the number of potential participants.

Creative tourism also implies some sort of involvement and engagement that can be very demanding. Accordingly, there is no reason to think that creative tourism can suffer from the adverse effects of mass tourism. Equally, the activities demanded by this type of tourists are not linked to seasonality, so destinations can have visitors all through the year and maintain their authentic atmosphere.

Creative Tourism and Economic Aspects

Tourism is one of the most important industries in many countries, with a very significant impact on many other sectors. As in any other business, one of its main concerns is getting economic benefits, the more, the better. Creative tourism is no exception, and it has been considered a development tool to improve national economies, regions, and cities.

It can have a significant effect on rural areas, and there are initiatives all over the world that have confirmed outstanding results, with essential increases both in tourism visits and revenues. Very frequently, these proposals are organized in creative clusters, making places more appealing to attract visitors and therefore, contributing to the improvement of the local economy.

These types of creative tourism initiatives frequently have a positive impact on the image of regions and cities from many different points of view, so they are frequently supported by the economic development division of the regional or city government. A significant number of cities, regions, countries, and worldwide organizations have laid the foundations for the emergence of new initiatives and the coordination and dissemination of creative development projects.

With the aim of improving the economy in rural areas, some studies emphasize the need not only to plan a well-developed original tourist structure based on authentic experiences to attract visitors but to establish a quality of place perspective to attract permanent residents, specifically the “creative class.” Creative workers can create new businesses and attract new firms to the area, generating more wealth. Sometimes creativity can stimulate local development and entrepreneurial initiatives. It can avoid the exodus of young people, depopulation, and lack of economic resources and become an essential economic driver for the local economy, with an increase of start-ups and spin-offs in creative industries.

Creative tourism approaches can also play a significant role in cities from an economic point of view. Although cities usually have many other interesting attractions for visitors, creative experiences undoubtedly present new options for potential travelers.

The type of business/economic structure that is usually involved in creative approaches is a small-scale tourism business that allows different kinds of entrepreneurs to set up and run their own company.

Especially significant is the case of lifestyle entrepreneurs who base their activity on their hobbies and interests, sharing their knowledge and passion with others. Making huge profits is not their primary concern. Lifestyle motives (living in a specific selected area, being their own boss, or working in something related to their interests) are their motive. Their activity is generally based on different types of creative products and approaches, such as painting or photography holidays, gastronomic experiences, spiritual or “holistic” holidays, and so on.

However, it is also essential to take into account that cultural and creative industries are somewhat vulnerable in economic terms and can suffer quite a lot in economic crisis. For the consumer, creative experiences should be something unique, stimulating, fun, memorable but also affordable.

Effects on Tourists

Effects on Tourists from Promoters' Point of View

As we mentioned earlier, most studies that try to establish the links between creativity and tourism focused on the points of view of tourism industry agents (products, providers, etc.), leaving aside quite often the tourists' views.

A highly relevant element for tourists is the impression left by the different experiences that took place during their trips. The lived episodes that are worth remembering will make tourists long for revisiting those places, motivated by the positive memories.

One of the main concerns of the industry is fostering the tourists' intention to revisit and recommend the destination, and creative tourism can constitute an excellent contribution to achieve this objective. If creative tourism experiences are memorable, tourists will want to repeat the experience and rely on the same service providers.

Different scholars have pointed out the need for more studies on creative tourism that pay attention to the tourists themselves, as very few place them in the dominant role that they should have.

This line of research highlights the need to take into account what tourists want (Tan et al., 2013) and emphasize the importance of the experiences of creative tourists and the influence of these experiences on their memories, satisfaction, and behavioral intentions, such as revisit intention and positive word of mouth (Ali et al., 2016).

The critical issue is getting to know why tourists choose creative tourism products or experiences, although, as we mentioned earlier, there are reasons to think that tourists make this choice in coherence with what they do in their real life.

Can Tourism Improve Creativity?

It is important to note that not all forms of tourism can lead to creative development. On the contrary, for creativity to be triggered, there must be several conditions, based on interactive experiences that are not commonly present in most tourist products. They are normally restricted to specific creative tourism proposals that the active tourist has to search for and engage in. These experiential products, deeply rooted in authenticity, have to imply diversity, cooperation, cocreation, and coperformance.

Research highlighted (Campos et al., 2018) that the process of cocreation before, during, and after the trip is especially satisfying and memorable for tourists. Collaborating with tourism providers to tailor the trip, participating in interactive and creative activities in the chosen destinations, and sharing the experience on return can be excellent allies to foster creativity.

Especially thought-provoking is the idea that the interaction and cooperation with different cultures that tourism induces can lead to creative thinking and behavior. Evidence from studies on multiculturalism suggests that when an individual is immersed in a different cultural context, he or she has a positive attitude toward it and is willing to broaden his or her horizons and experiences; the new surroundings will open up a world full of new perspectives that can positively contribute to trying new ways of thinking and other strategies to solve problems. In a nutshell, multicultural learning can be an excellent ally in creative development, especially when there are different experiences with a wide range of cultures. Although these studies mainly refer to situations

in which people spend some time living in the country, it leaves a door open to consider that something similar may occur on shorter trips when the creative tourist possesses the right attitude to be integrated with a new culture in an interactive way and with an adequate mindset.

Accordingly, the evidence seems to suggest that to widen their creative potential, tourists should seek more than just superficial contact with the other culture, maintain an open mind to experiences, have a positive attitude toward the other cultures, and participate in interactive situations.

However, even if tourists have not been involved in creative tourism experiences, the simple act of traveling can stimulate creative behavior. For many tourists, the change that traveling implies inspires them to transmit it to others using the endless resources that the information and communication technologies (ICT) have placed at our disposal. In this way, they generate different types of digitalized original materials through the web, referred to as tourism-created content. The resulting product can be presented using three different formats: narrative, visual, and audio (Munar, 2011). The relationship between traveling and creative production has existed for a long time. Travelers used to keep a written record of their trips, a diary or travelogue giving way to the origin of a new literary genre, travel literature, back in the 18th century. Just the privileged few who could afford to travel at those times were in a position to write.

Something similar occurred in the production of documentaries, films, video, or photography. Some years ago, technology-supported visual arts were reserved to just a few, but nowadays, ICT have opened sophisticated and accessible possibilities to convey information and manipulate materials, becoming the best ally for creativity development.

From an artistic point of view, more does not mean better, but undoubtedly, thanks to the combination of more accessible ways to travel and almost universal access to the Internet and ICT, the situation has completely changed. Many people can channel both their desire to travel and their creative germ, making it possible to experiment and put into practice ideas that would remain, otherwise, dormant.

Advantages and Limitations

Advantages

In addition to the numerous social, cultural, and economic benefits that can be accrued thanks to the mediation of creativity-based initiatives, as we have seen, the advantages of creative tourism are primarily linked to its unique, authentic character, what makes unlikely that the same activity can be reproduced elsewhere, limiting the appearance of serial reproduction. In this way, its competitive advantage is more achievable and its risk of failure less likely.

On the other hand, tourists can have a completely different experience, having the option of being immersed in the daily life, culture, and traditions of the chosen destination. Likewise, tourists have more contact with locals, establishing an enriching participative interaction between them. In this way, creative tourists can experience the detonation of their creative potential and obtain a feeling of personal fulfillment that will induce them to try to relive the experience.

Limitations

Very often creativity is seen as a marketing strategy, and tourism developers and policymakers can use its current allure to foster projects and initiatives that are not deeply rooted in the real spirit and essence of locations and populations. The hype is such that no in-depth studies are carried out to check and justify the convenience or need for these proposals. In these cases, creativity can become a fake version of some other more genuine enterprises that some try to emulate. It is not a natural consequence of the genuine interests and lifestyles of cities and regions but an external booster provoked by both the media and academics.

This position can lead as well to homogenization, or serial reproduction, mainly caused by artificial actions. It is true that the features of creative tourism and their experiential, interactive facets require some intervention to encourage creative tourists' participation because they are not merely passive consumers but active cocreators.

In addition, several studies (Richards and Wilson, 2007; Dias-Sardinha et al., 2018) have highlighted several barriers to creative development: the shortage of creative skills, the lack of creative investment and audiences, and the cumulative disadvantage of creative locations.

Besides, very often, the lack of specific local policy regarding specific types of heritage and the absence of cross-sectoral collaboration and cooperation constitute a limitation for creative tourism development.

In rural areas, excessive mercantilism can derive in a loss of authenticity and idyllic atmosphere.

Regarding the impact of creative tourism on tourists and locals, very often the tourists do not experience any transformation either from a creative point of view or an intercultural perspective. For locals, sometimes it can even have negative consequences as part of their authenticity can be lost if the emphasis is put on the marketing and commercial side.

Developing a creative product, city, or region is much more than placing the adjective "creative" before the noun because it is fashionable and trendy nowadays. As we saw, a thriving creative project requires a thoughtful analysis of all the elements that come into play to produce something unique, interactive, experiential, and cocreative based on authenticity. In order to achieve this purpose, it is mandatory that both the tangible and intangible aspects of culture are fully respected to be able to genuinely transmit to our descendants what we learned from our ancestors.

Conclusions

A perfect symbiosis between creativity and tourism is necessary to take into account a series of concepts, mentioned throughout the text, that can be considered fundamental for creative development and responsible tourism. The more features the tourism experience includes the more options for creativity to be fostered and increased. They can be recapitulated in the following graphic:

It is also especially significant to take into account that creative tourism does not necessarily imply the development of significant infrastructure or large investments. New projects are frequently based on exploiting the numerous existing authentic resources, applying creative formulas with the aim of attracting both professionals from the creative sector and tourists with an open mind, willing to be integrated into a new stimulating experience that will make them feel fulfilled in the personal and professional arena. In this way creativity dominates the whole process, producing new opportunities for destinations and their residents, promoting the establishment of creative professionals, and awakening and fostering tourists' creative potential.

Introduction: Creativity as an Applied Science

With the advent of the 21st century, interest in harnessing the practical benefits of creativity has reached heights never seen before. While 20th century proponents of applied creative-thinking methods, pioneers such as [Alex Osborn \(1953\)](#) and [Edward de Bono \(1985\)](#), worked to extol the importance of creativity, today creativity is commonly cited by educational, business and governmental leaders as a crucial workplace skill. Indeed, a recent report produced by such global leaders projected Creativity to be the third most important work skill in the year 2020 (see the World Economic Forum's 2016 report *The future of jobs: Employment, skills and workforce strategy for the fourth industrial revolution*). Contrasting the WEF's 2020 list of career skills to their 2015 projections, it is worth noting that Creativity climbed the greatest number of ranks, among all skills, moving from 10th to third most important. The critical role creativity is predicted to play in the workplace is underscored by the fact that the WEF 2020 list includes additional skills that are highly-related to creative thinking (e.g., #1 Complex Problem Solving, #5 Coordinating with Others, #7 Judgment and Decision Making, and #10 Cognitive Flexibility). The WEF is not alone in its clarion call for creativity. Dozens of reports, studies, and books have all reached the same conclusion: creativity is among the top success skills in the 21st century ([Puccio, 2017](#)).

In the 20th century only a few creativity pioneers were proponents for applied creative thinking, yet in the early 21st century there is almost a universal call for creativity. What has fueled this dramatic rise in demand for applied creativity? Simply put, in a world increasingly defined by complexity, uncertainty and volatility, creativity has become a survival skill ([Puccio, 2017](#)). It is now argued that we live in an innovation economy ([Janszen, 2000](#)), and as such the pace of change has expanded at an exponential rate. New technologies, business models, products and services come to fruition and then fade away, faster than ever before. In today's economy, innovation is seen as the route to prosperity and it is widely accepted that creativity is a key catalyst to innovation ([Puccio and Cabra, 2010](#)). To successfully keep pace with change, organizations and societies across the globe are striving to become more innovative; however, innovation occurs only when the creative potential of individuals is allowed to flourish ([Puccio et al., 2018b](#)).

The increased demand for creativity appears to seriously exceed the supply. Findings from a number of studies highlight a skills gap that now exists between the need for creativity in organizations and society as a whole, and the degree to which individuals have been prepared to fully engage in this 21st century ability. To illustrate this point, here are a small number of findings that underscore today's creativity skills gap. Whereas Human Resource managers include creativity among the 14 most important applied skills for new employees, nearly 70% say they don't know how to develop this crucial skill ([Casner-Lotto et al., 2009](#)). Although MBA recruiters identified creative problem solving as one of the top five most desired workplace skills, they also indicated that it's the second most difficult skill to find ([Otani, 2015](#)).

Finally, a series of international surveys carried out by Adobe with students, employees, educators, hiring managers and policy-makers highlighted the creativity skills gap is both considerable and global in scope (see Relevant Websites). With respect to the importance of creativity, 80% of adult respondents felt creativity was crucial to economic growth and 78% believed it was critical to career success. Given this very positive perception of the value associated with creativity, it is regrettable that only 25% of respondents felt they were living up to their creative potential. Sadly, the survey respondents' views of their educational experiences may explain, in part, why they may not be able to fully exercise their creative potential. When asked about the impact of education on creative thinking, 52% of global respondents said their creativity had been stifled by their education (75% in the United States). The need for creativity in an innovation economy, in conjunction with the creativity skills gap, has created growing opportunities for creativity professionals (i.e., experts who are knowledgeable about the nature of creativity and possess the skills to nurture creative talent and outcomes in others). As a consequence, career and commercial opportunities now abound for those professionals who have developed expertise relative to applied creativity.

Professional Roles for Creativity Practitioners

To inform the writers' understanding and personal experiences with the field of applied creativity, Puccio and Switalski surveyed a sample of 50 creativity professionals, mainly based in Europe, North and Central America. They followed up with a focus group aimed at deepening our understanding of the findings that emerged from the survey. Much of the remainder of this entry is informed by the qualitative data gleaned from interactions with these 50 creativity professionals. This review begins by looking at the four professional roles most often assumed by creativity practitioners: Training, Facilitating, Consulting, and Coaching.

Training focuses on the development of creative attitudes, thinking skills and behaviors of the workforce. Creativity training is designed to address the need to develop employees' creative capabilities as applied to their everyday work responsibilities, such as identifying new opportunities, becoming better problem solvers, daring to challenge accepted practices and procedures, and exploring new pathways that lead to innovative outcomes. From the practitioner's standpoint, training encompasses designing and delivering learning sessions that teach people to embrace a mindset that is curious and adaptable to change, as well as to apply and facilitate creative processes, tools and techniques. Training programs are often based on well-known applied creativity methods, such as Creative Problem Solving, Design Thinking, Agile, Lego Serious Play, Lateral Thinking, and Biomimicry. And there is ample evidence to show that creativity training works. In particular, creativity training that is based on cognitive models, like Creative Problem Solving (Puccio et al., 2018a), are among the most effective programs. A meta-analytic analysis of creativity training programs demonstrates that such training has four main areas of impact: divergent thinking, attitudes, problem solving, and creative performance (Scott et al., 2004).

Increasingly creativity training involves the use of technology, teaching people to apply the creativity process on a digital platform, and incorporates the use of graphic facilitation tools. Creativity training programs can range between day-long engagements to several months, and is often supported by individual coaching sessions. Finally, given the transdisciplinary and cross-functional value of creativity, creativity training has been embedded in and used to accentuate training in other subject areas, such as leadership development, project management, sales effectiveness, conflict resolution, support group facilitation, strategic thinking, communication and public speaking, collaboration and team effectiveness, and change management.

Facilitating lies at the core of the services offered by a creativity practitioner. Facilitators are charged with guiding a group through a process designed to enhance collaboration among group members so that the output of their thinking achieves optimal results for the task at hand. To that end, facilitators use their expertise in deliberate creative processes and methods, such as Design Thinking and Creative Problem Solving, to lead a group of individuals through a series of steps designed to produce creative outcomes. When facilitating creative process sessions, creativity facilitators utilize a wide array of creativity tools and techniques that are intended to enhance participants' creative-thinking skills as applied to the content of the meeting. Facilitation services can be applied to a variety of subjects and tasks, such as idea generation sessions, new product or service development, problem solving, strategic planning, process improvement, and vision setting. More broadly, creativity facilitators are often hired simply to guide meetings that improve communication and collaboration within a team. From the client's perspective, facilitation services are results-oriented, i.e., they are expected to attain a desired outcome. From the practitioner's standpoint, facilitation services are process-oriented, i.e., guiding a group's thinking, managing group dynamics, and creating the physical and psychological environment that supports creative thinking and creative behavior.

Consulting represents a more recent expansion in services offered by creativity professionals, as they blend their knowledge and practice of creativity with their experience in the sector of organizational development. Creativity consulting focuses on supporting organizational transformation and change, with particular attention to culture and workplace climate. It responds to the growing interest in building an organizational culture that is innovative and entrepreneurial. The consultative work provided by creativity professionals can also be focused on assisting organizations to be more successful in bringing change initiatives to fruition. Creativity consulting often involves the use of assessment methodologies (i.e., climate surveys, personality type and cognitive style measures, 360 leadership evaluations, one-on-one interviews, focus groups, etc.) to diagnose the current reality of an organization and to identify the desired future state. Based on this data collection and analysis, the creativity consultant designs strategies to achieve the desired outcome and monitors the implementation of the devised plan. Consulting services represent systemic and strategic engagements with organizations and therefore are generally broad in scope and long-lasting. Consulting services typically intertwine with training, coaching, and facilitation services. As such the initiatives led by creativity consultants are deployed across multiple levels and functions within organizations, and are designed to transform individual employees, teams, and the organization. Team effectiveness and leadership development programs are often included in creativity consulting services. Since creativity consultation is strategic in nature, the request for such services generally comes from, and is championed by, senior leaders within organizations.

Coaching is a more recent role adopted by creativity professionals. Building on the mounting success and popularity of coaching services in general, creativity coaching is commonly used to accentuate and support training and organizational development interventions. Coaching engagements are one-on-one programs in which a coach specifically focuses on the learning and professional development goals of an individual. With this end in mind, creativity coaches often serve as facilitators to their clients. In support of this role some coaches actively use creativity processes and methodologies, such as Creative Problem Solving, in their work (Chmielewska and Modrzejewska-Swigulska, 2014). These tools help coaches guide the problem-solving efforts of their clients and, when internalized by clients, enables them to attain greater levels of creative self-efficacy. Creativity coaches use reflective dialog to empower individuals to strengthen their creative mindset, to effectively apply their creative-thinking skills, and to support the

success of organizational change initiatives. A growing trend among creativity coaches is to engage in team coaching. Here creativity professionals support all members of a team as they collectively apply their creative thinking to resolve organizational challenges.

Experienced creativity practitioners tend to play various professional roles, as described above, and thus offer a range of services. As the field of applied creativity has grown, creativity professionals have become more well-rounded and sophisticated, blending creativity practices across fields and integrating creativity approaches to any service they offer. Creativity professionals can follow two alternative career pathways, external or internal to established organizations. A majority of creativity practitioners choose the former, more entrepreneurial career path. External creativity practitioners work as independent contractors who offer their services to multiple clients. They may work independently within a network of colleagues or in relatively small-size consulting firms.

Focus group findings reinforced the fact that as the field of applied creativity matures there is a corresponding increase in the number of creativity professionals who work within established organizations. With competitive pressures forcing corporations to become more innovative, these internal roles are mainly found in the for-profit sector. However, some not-for-profit and educational organizations have created professional roles for creativity practitioners. Generally, internal creativity professionals either have part-time or full-time job responsibilities in work units that serve an innovation function or in more traditional departments, such as learning and development. Internal creativity professionals provide a range of services, such as the aforementioned skills of training, facilitating, consulting, and coaching, but under the umbrella of a single organization.

Becoming a creativity professional is the result of a deliberate approach that requires considerable investment of energy, time, and money. Many of the practitioners surveyed pursued a formal accreditation process through master's degree programs or certificate programs granted by established academic institution. Others sought long-term training programs that require the participant to follow a multi-level learning pathway and demonstrate the acquisition of facilitation, training or coaching skills. Such programs typically provide certification from associations or institutes with expertise in the fields of coaching, creativity, and facilitation. Most of the practitioners surveyed engaged in ongoing professional development activities. For instance, many reported regularly attending creativity conferences where they have the opportunity to meet and network with their colleagues, broaden their toolkit, and deepen their skillset. Additionally, many creativity professionals attend programs that certify the use of assessment methodologies, such as inventories that measure personality type, cognitive style, psychological climate, and emotional intelligence. Finally, most creativity professionals continue to expand their knowledge base and tool kit by learning and applying new approaches to applied creativity as they emerge.

Occupational Description and Benefits of Being a Creativity Practitioner

Data gathered from the survey of 50 creativity practitioners confirms that the majority were self-employed (71%) and dedicated a high percentage of their time (75%–100%) to their work as creativity professionals. The most common job titles used to describe their work were 'Creativity Facilitator' and 'Innovation Consultant'. The combination of words selected for their job titles is informative. For instance, the wide adoption of the term Creativity Facilitator provides a clear indication of the ways in which creativity practices have been integrated into the broader category of facilitation work (Schwarz, 1994). Those who serve as Creativity Facilitators are focused on leading process engagements for groups. In contrast, the consultative role is mostly associated with the word Innovation. Here, the creativity professional guides a transformative process to achieve innovative outcomes that respond to an organization's overarching strategy.

Over the years, the use of the word Creativity seems to have encountered broader acceptance in the business world. Nevertheless, most clients tend to show a preference for the word Innovation, which better aligns with their expectations for tangible results to be derived from the services provided by creativity professionals. Thus, regardless of the job title adopted by creativity practitioners, the sample of creativity professionals indicated that they often use the word Innovation in their discussions and proposals when positioning their services to prospective clients. As one participant in the focus group pointed out, "Clients care about the outcome, they do not ask for creativity, they ask for effective problem solving, change, and innovative results."

The number of clients served per year by a creativity professional, one working independently or in a small consulting firm, can range from a few (up to 5) to many (more than 15). The survey of creativity professionals indicated that the number of clients served was not related to years of experience. Rather, it was more likely to be contingent upon the type of services provided by the practitioner (i.e., short-term training and facilitation services versus long-term consulting and coaching engagements). That said, experience in the field predicted the amount of money earned for creativity services. Professionals with over 10 years of experience report charging daily rates above \$4000, while practitioners with less than 10 years of experience were more likely to set their daily rate up to a maximum of \$3000. When it comes to fees for services, geographical location seemed to play a role as well, with creativity professionals in North America reporting higher rates than their counterparts in Europe and Central America. This geographical difference may reflect the fact that creativity professionals in North America benefit from a more competitive and mature market which allows experienced professionals to garner greater compensation for their services.

Beyond monetary rewards, respondents emphasized two main benefits associated with their work as creativity professionals: personal satisfaction with the nature of the work itself and the sense that their work has a positive impact on others. People who work as creativity professionals share a great passion for their careers which translates into high levels of joy and fulfillment. This sense of satisfaction was accentuated by the second benefit associated with the work carried out by creativity professionals, which is the sense that they assist individuals, teams, and organizations achieve meaningful goals. Creativity professionals take pride in the fact that through their work they help others achieve positive change, both at individual and organizational levels.

A participant in the focus group summarized the creativity professional's sense of accomplishment by saying, "Creativity is a life skill that has profound influence on people's lives. The impact we have working with people might go beyond the results achieved at work. It can spread to their personal lives and positively affect their family and the community they live in."

Future Trends

The future for creativity professionals looks bright. As the world enters a fourth industrial revolution, with artificial intelligence and other forms of technology playing even greater roles in personal and professional lives, the demand for creativity skills is likely to grow. With that in mind, there are at least four important future trends that are likely to influence, and potentially expand, the kind of work carried out by creativity professionals.

First, the field of creativity studies is transdisciplinary in nature, and thus it is expected that creativity professionals will find even greater opportunities to blend creativity practices into a wider array of subjects, functions, and fields. No longer is creativity simply associated with the arts or with the R&D function found in organizations. As the National Center on Education and the Economy (2008) reported, "Creativity, innovation, and flexibility will not be the special province of an elite. It will be demanded of virtually everyone who is making a decent living, from graphic artists to assembly line workers, from insurance brokers to home builders" (p. 25). Given the broad implications and applications of creativity, it is likely that future creativity professionals will provide their services to an ever-expanding set of markets and audiences.

Second, there is a movement towards greater levels of co-creation. These are collaborative processes in which organizations, both for-profit and not-for-profit, partner with end users, consumers, and stakeholders to co-develop creative solutions. By nature, these collaborative processes are highly complex as they bring together individuals with diverse expertise, perspectives, needs, and expectations. It is likely that creativity professionals will be in a position to enhance the effectiveness and outcomes of co-creative initiatives by providing training, facilitation, consulting, and coaching services.

Third, employee engagement represents an area of growing concern among organizations. At the same time, there is clear and compelling evidence that allowing employees to use their creative capacities at work improves intrinsic motivation and satisfaction (Amabile and Kramer, 2011). Given this link, it would seem that creativity professionals might be able to support organizational development initiatives aimed at improving engagement by drawing on the creative talents of all employees, not just those in traditional innovation functions. This emphasis on creating work situations that allow for greater levels of creativity may become more important as the workforce is filled by members of Generation Y and Z. Both generations have been described as being more independent-minded and entrepreneurial than past generations.

Finally, the nature of leadership is determined by the context, and in a complex and fast changing world it may be time for a new kind of leadership to emerge – Creative Leadership (Puccio et al., 2017). Creative Leaders are those individuals who engage their own and others' creative-thinking skills to drive organizational change. Furthermore, by modeling the way Creative Leaders foster work environments that support creative behavior and innovative thinking. The relevance of creativity to leadership was highlighted by a 2010 IBM study of more than 1500 executives. This global study of private and public sector leaders produced the resounding conclusion that creativity is the most important leadership skill going forward. To build organizations that are truly innovative, and not to simply play lip service to innovation, it will be imperative for leaders to adopt more creative attitudes and skills. Here creativity professionals can play a crucial role in developing such future leaders and leaders of the future.

The Transforming Illness

Nietzsche's phrase "What does not destroy me, makes me stronger" is evident in the transformational power of major illness. Throughout the centuries visual artists of diverse backgrounds have used creativity to turn poor physical health into a transforming illness, an experience that alters both their lives and their work. There are as many types of transforming illnesses as there are people who have them. Artists have used conditions such as cancer, AIDS, arthritis, quadriplegia, learning disorders, vision problems, deafness, and the aftermath of serious accidents as opportunities for self evolution (Zausner, 2016; Sandblom, 1996). A transforming illness may be an acute episode or a chronic condition, yet whenever it appears, life takes a new trajectory and things are never the same.

Transformation occurs through an interface between an illness and a person's creative response to the illness, with specific aspects of the physical condition influencing both the creative process and the art produced. Some individuals have become eminent artists after a major illness while those that were already practicing professionals have had their way of working altered and their art deepened and changed. The transforming illness can occur at any age from the beginning of life to its end and may happen more than once. By using creativity and physical illness as a combined impetus for transformation, artists can alter their personal experience, self-expression, and ultimately cultural history.

Aspects of the Transforming Illness

There are multiple aspects to the transforming illness such as resilience, using creativity as coping mechanism, self efficacy, mastery, compensation, and the experience of flow. Using a debilitating physical condition to improve both your life and work is an example of resilient behavior. Resilience is the capacity to bounce back from setbacks and adapt to events in life that are neither comfortable nor planned. Artists will often use creativity as a coping mechanism during illness to manage stress. Our minds can generally focus on only one thing at a time, which makes creativity an excellent coping mechanism during illness because it can distract a sick person from physical discomfort by redirecting attention toward a creative activity. The folk artist Maud Lewis (Canadian, 1903–70), who is the subject of the 2016 biographical film *Maudie*, had a lifetime of pain from severe juvenile rheumatoid arthritis. Yet she spoke about her art as a distraction from pain saying, "As long as I've got a brush in front of me, I'm all right." Arthritis became a transforming illness in Lewis' childhood because she turned to art to pass the time when poor health kept her home from school. Despite severely limited use of her hands, Lewis became a professional artist. Preferring to use her right hand to paint even though her left hand was less affected by arthritis, Lewis propped up her right hand with her left one to keep working.

[☆] *Change History*: June 2019. Tobi Zausner updated the text throughout the article.

This article is an update of T. Zausner, Transforming Illness and Visual Art, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 489–495.

The distraction that artists experience during creativity is explained through what the psychologist Mihaly Csikszentmihalyi (2013) describes as a time of flow. In this enjoyable state where self-consciousness fades away, people can become involved in a task to the extent that they have a diminished awareness of stimuli from the outside world. The positive feeling engendered during a state of flow acts to further whatever activity is generating the experience. When creativity produces the state of flow, it becomes an impetus to continue making art.

The creative expression that takes place during illness can also be a welcome experience of self efficacy and mastery, imparting a feeling of strength that counteracts the weakness stemming from physical problems. In addition, artists have used the subject matter in their work as compensation for activities they feel have been denied them because of illness. After a debilitating traffic accident that required a long convalescence, the painter Frida Kahlo (Mexican, 1907–54) said, “As the accident changed my path, many things prevented me from fulfilling the desires which everyone considers normal, and to me nothing seemed more normal than to paint what had not been fulfilled.”

Making art during illness can become a healing experience, which like the state of flow, further encourages the activity. The French painter Henri Matisse believed that not only was creativity healing but so were its products. He would hang his work around the beds of sick friends because he was convinced the bright colors would help them feel better as they did for him when he was sick.

The Early Transforming Illness

Many eminent artists began their careers as the result of an early illness. Some conditions were present at birth while others were contracted. Yet in all cases the artists used creativity to pass the time when they were sick. The early transforming illness differs from its occurrence in adulthood because it is necessary for the child to have at least one attentive caregiver. In examining the lives of resilient children who came from backgrounds of hardship, the psychologists Emmy Werner and Ruth Smith found each resilient child had at least one nurturing relationship and that this supportive relationship was life changing for them. For young artists, the caregiver was not only nurturing but also encouraged the child’s creativity and provided art supplies, which can be pivotal in an early transforming illness.

When Andy Warhol (American, 1928–87) became sick at age eight the art supplies his family gave him during his long months of convalescence shaped the work he would create as an adult. Warhol had rheumatic fever which progressed to chorea, an illness of the central nervous system that caused violent tremors. Although they were of very modest means, his mother believed that creativity would help him recover. She gave him coloring books, comic books, paper doll cutouts, and movie magazines while his brother Paul gave him a camera and taught him art techniques. As an adult, Warhol’s paintings had black outlines and swatches of color like coloring books; he made images of movie stars and comic book characters; the camera became central to his work, and he used paper doll cutouts in his early graphic design.

At age eighteen, Frida Kahlo (Mexican, 1907–54) was severely injured in a traffic accident. Incapacitated for months, her mother had a carpenter build an easel for her to use in bed and her father, a photographer and amateur artist, gave her his oil paints. Kahlo had been a pre-med student until she began making art during her convalescence. “Instead of studying to become a doctor,” she stated, “And without paying much attention, I began to paint.” Kahlo had a prior transforming illness at age seven when she contracted polio and began to draw. Her father encouraged her talent and taught her how to use a camera. Even though Kahlo sketched constantly and took art lessons she planned on a career in medicine until the traffic accident altered her life.

Mobility problems early in life also turned Henri de Toulouse-Lautrec (French, 1864–1901) to a career in art. Research suggests he had pycnodysostosis, an inherited condition producing brittle bones that heal poorly, problems with walking, and dwarfism. Unable to be athletic like his relatives, Lautrec was instead a periodic invalid throughout his early years. Then his condition worsened because of two falls he sustained as a teenager that broke his leg bones. Lautrec’s uncle, an amateur artist, had given him art lessons since early childhood and during his convalescence from the accidents he focused on creativity. Acknowledging the role of illness in his life, Lautrec insisted, “One thing is certain, if my legs had been a bit longer I would never have become a painter.”

Parental Pressure, Illness, and Careers in Art

For some individuals, whose families wanted them to follow more secure and established professions, it was an illness in childhood and young adulthood that halted parental pressure and allowed them to become artists. The desire to see a sick child recover was paramount to the caregivers, even if it meant that the young person would choose a less secure vocation. When Lawrence Alma-Tadema (English born in Holland, 1836–1912) developed tuberculosis as a boy, his family believed he had not long to live. In response they allowed him to stop preparing for a career in law and take art lessons. Alma-Tadema’s health recovered, and he became a professional painter. George Tooker (American, b.1920), who had suffered from ulcerative colitis and a chronically inflamed appendix since childhood, acceded to family pressure to have a career in finance although he wanted to be an artist. When Tooker’s intestinal problems became extremely severe in his early twenties, his parents relented, and he began a career in art.

As a teenager, Henry Ossawa Tanner (American 1859–1937) knew he wanted to be an artist but his family pressured him to be a businessman. He had been a sickly child and the stress of painting at home while going to work severely compromised his health. Tanner’s parents, fearing he might die, gave in and permitted him to become an artist. Tanner had a second transforming illness in his early twenties. As a young artist painting in Paris, he contracted typhoid fever and went home to Philadelphia to recuperate. It

was on this trip home that Tanner reconnected with his African-American heritage and celebrated his ethnicity in the best-known paintings of his career. Although all of these men were very sickly as children, they found art to be healing and all three of them lived long lives.

Eye Problems in Childhood and Their Influence on Art

It may appear paradoxical that an individual with poor eyesight would decide upon a career as a visual artist, yet this has happened repeatedly and with a variety of visual impairments. When the visual condition occurs in childhood, then as with other early illnesses, it is important to have an encouraging and nurturing caregiver, one who focuses on the young person's desire for creativity rather than on the presence of a visual disorder. Albert Pinkham Ryder (American, 1847–1917) had the good fortune to have such a caretaker in his father. When Ryder developed a severe inflammation of both eyes in response to a childhood vaccination, his father, knowing that his son liked to draw, gave him art supplies. The gift changed Ryder's life. He said, "When my father placed a box of colors and brushes in my hands and I stood before my easel with its square of stretched canvas, I realized that I had in my possession the wherewith to create a masterpiece that would live throughout the coming ages." Ryder's eyesight remained problematic throughout his life. Unable to see fine lines, he used broad areas of color and painted from his imagination. Ryder's poor vision created strength in his art.

When Matthew Brady (American, c.1823–96) was a teenager, he also had a severe eye inflammation and turned to art. While making a trip to find medical care, Brady met the painter William Page, who encouraged the boy and gave him art lessons. Later, in his twenties, Brady changed from painting to photography. With diminished sight he needed assistance to focus the camera and adjust the dials, but it was he, who arranged the poses, composition, and lighting. Although Brady is well known for his portraits of Abraham Lincoln, his most famous photographs are of the Civil War. While both Ryder and Brady had lifelong vision difficulties, sometimes an eyesight correction can turn a child to art.

Nell Blaine (American 1922–96) said two things influenced her to become a painter, "One was making art when I was a sick child in bed and the other was the improvement in my eyesight from glasses and operations." When Blaine was finally able to see well, the world looked so beautiful to her that it became the subject of her art for the rest of her life. Sometimes eyeglasses can only give a partial correction as they do with Raymond Hu (American, b. 1977), who works with his eyes just inches away from the paper. Yet with parental encouragement, art lessons, and supplies, Hu started making art as a teenager and continues working today. Despite the poor fine motor control that is associated with his condition of Down syndrome, Hu perseveres and forged a new watercolor technique combining Asian and Western elements.

Learning Difficulties: Dyslexia, Attention Deficit Disorder, and Prosopagnosia

Learning disorders have also turned individuals to art. They are widespread, affecting about 10 to 30 percent of the population with dyslexia being the most prevalent. Dyslexia, which is usually inherited, is noted by problems with reading, spelling, and writing. Now a recognized learning problem, people with dyslexia in the past were often considered to be less intelligent even though some of them like Leonardo da Vinci (Italian, 1452–1519) were geniuses. People with dyslexia often have difficulty learning a foreign language and Leonardo, who appears to have a type of dyslexia known as surface dysgraphia, could never master Latin. As a result, he could not enter his father's profession of a notary nor attend university where classes were given in Latin. Instead, Leonardo decided he would become a "disciple of experience" and do his own empirical research rather than quoting the work of others. Focusing his keen mind on the natural world, he recorded notebooks filled with scientific observations (Vasari, 2008). Leonardo also became an artist, a profession where education was not written in Latin but given orally in Italian.

Leonardo also appears to have a mixed form of attention deficit disorder that contains both daydreaming and restlessness as well as the ability to hyperfocus, which is the capacity to concentrate for an extended period. While Leonardo's restlessness often prevented him from finishing long term projects, it helped him create short term works such as drawings. By the end of his life, Leonardo made over four thousand drawings, a number four times greater than any other individual of his time. Leonardo employed his ability to hyperfocus during the long hours he is recorded as working on his art. He used his propensity to daydream to create inventions such as his machines. When assembled over five hundred years later from Leonardo's original drawings, these machines work perfectly.

The sculptor Auguste Rodin (French, 1840–1917) also had dyslexia. His parents wanted Rodin to have a career in the professions or civil service. Although Rodin eventually learned to read, he was unable to master Latin, spelling, or mathematics. Realizing this, his parents allowed him to study art. Both Rosa Bonheur (French, 1822–99) and Pablo Picasso (Spanish, lived in France, 1881–1973) had dyslexia. Yet Bonheur and Picasso may have become artists even without learning disorders because their fathers were professional painters who gave them art lessons from an early age.

Dyslexia has also affected the career choices of contemporary artists. Greystone Elizabeth Abbott (American, b. 1959) became a ceramic artist in response to an academic impediment in college. Yet the dyslexia that spurred her career change brought out a connection to her Native American heritage that had lain dormant until she began decorating her ceramics with tribal imagery. Chuck Close (American, b. 1940), who has attention deficit disorder and dyslexia, received art lessons in childhood and insists that

"Art saved my life." In response to being considered an unintelligent, inattentive, and lazy student at school, Chuck Close worked long hours teaching himself to read. The discipline he developed as a child shape his disciplined work habits as a professional artist. Close also has prosopagnosia, which is an inability to recognize faces. People with prosopagnosia, also called face blindness, cannot see a face in its entirety but instead comprehend the face as comprised of many separate bits of information, which when combined create their perception of a face. Close's work is completely comprised of faces created from separate small bits of information that the viewer combines into a whole image, thus seeing a face prosopagnosically as does Chuck Close.

Adult Onset of Illness

When physical illness occurs in adulthood, either acute or chronic, it can change an established artist's way of working and may also bring benefits from what may have initially appeared to be a disaster. During the winter of 1894–95 Odilon Redon (French, 1840–1916) became ill and described his condition as "being struck by exhaustion like a thunderbolt." Prior to that time Redon had focused on black and white work but by the middle 1890's he had begun to use color. After 1895 color work became his dominant form of expression, and Redon stated, "I am leaving black behind me." Consuelo Gonzalez Amezcua (American born in Mexico, 1903–75) also had a transforming illness in adulthood. Amezcua was a sculptor who worked in limestone but inhaling the rock dust as she carved left her with breathing problems. Forced to change mediums, Amezcua started drawing and found she had a gift for color.

The ceramic artist David Drake (American, 1800–c.1870) was also a poet. Known as "Dave," he had a transforming illness while a slave in South Carolina. A master potter who created large clay vessels that were used to store food before refrigeration, Dave was the first African American ceramic artist to sign his vessels and the first to write poems on them. Sometime before 1857, Dave lost a leg, making it impossible for him to stand and kick the potter's wheel he used to shape his clay. Determined to keep working, Dave had Harry Simkins, a slave whose arms were disabled, kick the wheel for him. By 1859 Dave Drake was making the largest ceramic works of his life.

When the kimono designer Itchiku Kubota (Japanese, b. 1917) was having a second exhibition of his art at age sixty, he contracted acute hepatitis. While in the hospital Kubota thought about his work and decided to develop a new style of kimono design combining ancient Japanese techniques with French Impressionism and scenes of nature. Kubota, who became very successful, spoke about the influence of having hepatitis saying, "This was the time of deepest import in my life as an artist." Pierre-Auguste Renoir (French, 1841–1919) started to develop rheumatoid arthritis at age fifty-six and despite his efforts at exercise, the illness progressed. Sitting in a wheelchair with swollen immobile fingers, Renoir continued to work. With small gauze pouches to hold his brushes, the artist moved his arms rather than his wrists to make art. His son Jean Renoir admired his father's determination and said, "The more intolerable his suffering became, the more he painted."

Creativity in Response to Cancer

One of the most prevalent illnesses in adulthood is cancer. Currently it is estimated that about one out of every three women and one out of every two men will develop this illness during their lifetime. Like the general population, artists get a variety of cancers but for the following individuals, the illness becomes a challenge that they face with creativity in a variety of ways. Some artists change their way of working or use the work specifically to address their emotional response to illness, while others like Vincent Desiderio (American, b. 1955) find that having been sick has strengthened them emotionally. Desiderio, who had an aggressive type of nasal pharyngeal cancer, says that the ordeal of illness and treatment with chemotherapy and radiation was grueling but it changed him. He states he now lives in the present moment and has developed greater internal strength, saying he no longer requires "validation from outside."

Although they had different types of cancer, Darcy Lynn, Dan Savage, and Nancy Fried used art to depict their psychological response to illness and treatment to manage the stress. The images they produced were often graphic depictions of medical procedures, shunts, vomiting, and breast removal that also showed their emotional anguish. After they recovered, all three individuals who remain well today used the art they created during illness to give hope to others who were sick. In 1991 when Darcy Lynn (American, b. 1956) was diagnosed with Stage IV immunoblastic lymphoma, a non-Hodgkin lymphoma, she documented her entire treatment through a series of paintings and drawings. After her recovery Lynn gave lectures on the role of creativity in healing to medical personnel saying, "I fought illness with the best weapon I had – my art."

Dan Savage (English, b. 1982), who was twenty years old when he was diagnosed with an aggressive form of testicular cancer, also depicted his treatment. Creating daily images of medical procedures and his response to them, Savage says, "I accepted it and used it for inspiration." After his recovery, Savage became a public speaker to emphasize the necessity of early detection and treatment, saying "I show there is life after cancer." Nancy Fried (American, b. 1949) had cancer four times during the years of 1986 to 1990. She had three separate types of breast cancer and cancer of the appendix. In response she began making sculptures of her ordeal. She shows herself with one breast after a mastectomy, having severe burns from radiation, and depicts her agony about being sick. Her sculptures became widely known. Fried, who did not have breast reconstruction and refuses to wear a breast prosthesis, openly presents herself as a one breasted woman saying, "By making something private public, you find you aren't the only one."

Artists With AIDS

AIDS (Acquired immunodeficiency Syndrome) is a pandemic but nowhere it is more prevalent than in Africa. Thirteen South African women, members of the Bambanani Women's Group: Babalwa Cekiso, Thobani, Nomawethu, Victoria, Noloyiso, Non-dumiso Hlwele, Thozama, Bongwiwe, Bulelwa Nokwe, Ntombizodwa Somlayi, Ncedeka, Maria, and Nomonde, who contracted AIDS, made art in response to their illness. Their creativity was part of the Memory Box Project from the University of Cape Town. It was originally intended to be expressive arts therapy for dying individuals to help alleviate stress and build a legacy to leave their children. Then with the introduction of ARVs (anti-retroviral medication) the women started to recover. Despite the sometimes violent prejudice against people who are HIV positive, the women have used their art as a political statement to highlight the importance of extending medical care to other low income individuals with AIDS. They also want to encourage those living with HIV saying, "We want to teach people living with HIV how to live with HIV. We want people outside to know that it is not the end of the world."

Keith Haring (American, 1958–90) also made a political statement about having AIDS. A very successful artist with a strong interest in human rights, Haring created posters about AIDS awareness and established a foundation to continue his work. It is the Keith Haring Foundation which carries on his commitment to assist both AIDS organizations and children. John Dugdale (American, b. 1960) was a commercial photographer who used AIDS to change careers and do the fine art photography he always wanted. Despite the multiple opportunistic infections associated with AIDS that caused him to lose half of his hearing and eventually all his eyesight, Dugdale, who achieved success as a fine art photographer, insists that, "In illness there is an unbelievable opportunity for freedom and change."

Color Vision Deficiency and Its Influence on Art

One of the most common visual impairments is color vision deficiency, also known as color blindness. Usually an inherited condition, it affects one in ten men and one in two hundred women. The degree of impairment can range from a slight inability to see colors to a profound lack of color discrimination. Although people with color vision deficiency have problems perceiving color, they have an enhanced ability to distinguish gradations of light and dark along with an acute perception of textures and patterns. Color vision deficient artists use this acuity in the gradations of light and dark that empower their work.

One of the most famous artists in Western culture, Rembrandt Harmenszoon van Rijn (Dutch, 1603–69), is believed to be color vision deficient. A. Hyatt Mayor, a curator at the Metropolitan Museum of Art, who was the first to recognize this in Rembrandt's work, also noted that Rembrandt's difficulty in perceiving colors gave him an increased sensitivity to tones of light and dark. He said of Rembrandt that "seeing the world more or less in browns freed him to calibrate luminosity with a delicacy as expressive as any palette of colors." Color vision deficiency also helped Rembrandt with his etchings, which was a black and white medium in the 17th century.

Although it is unusual to find a female artist with color vision deficiency, Kaethe Kollwitz (German, 1867–1945) appears to have this condition. Kollwitz, who showed talent at an early age and wanted to be a painter, realized in art school that her color perception was flawed. She said, "In the painting class I made no progress. Color was my stumbling block." In response, Kollwitz stopped making oil paintings and focused on black and white and brown and white imagery in etchings, drawings, and lithographs. She also turned to sculpture, another medium without color in which she could excel. Paulanship (American, 1885–1966) also had color vision deficiency and changed to sculpture after difficulties with color in his paintings. Charles Meryon (French, 1821–68) was another artist with color vision deficiency who stopped painting and achieved success with his black and white etchings.

Lack of color in an artist's work cannot be used as the sole criteria to assess a person's level of color vision. Odilon Redon and Chuck Close worked almost exclusively in black and white for the first half of their careers before going on to become major colorists. Caravaggio (Italian, 1573–1610), born Michelangelo Merisi, showed an excellent sense of color in his early work but preferred a reduced palette emphasizing light and dark in his later paintings.

Artists With Macular Degeneration

Macular degeneration, which is a disease of the retina, is one of the most common causes of vision loss in older adults. In this illness, the macula, which is the central part of the retina, becomes damaged leaving the affected individual with only peripheral vision. Although this illness usually found in individuals over fifty-five, Edgar Degas (French 1834–1917) had his first symptom at thirty-six. The condition, which began in his right eye, eventually affected his left eye as well. Even without central vision, Degas was determined to work. Unable to stand the glare of the sun, Degas painted indoors, creating interior scenes, portraits, and images of ballet dancers. When his eyesight deteriorated so that he could no longer see the fine lines his brush made with oil paint, Degas changed to pastels where the thick chalk lines were easier to see. These pastels are his most popular works. As his vision worsened and Degas could no longer see the chalk lines, he turned to sculpture, using his hands to help his failing eyes in a determination to remain creative.

For most of her life Georgia O'Keeffe (American, 1887–1986) had excellent vision but in her later years, she developed wet macular degeneration in both eyes along with a rupture of capillaries in the retina of her left eye. Faced with diminishing vision, O'Keeffe started to simplify her forms. She also worked from photographs and from her memory saying, "You paint from your subject, not what you see." For a while O'Keeffe, like Degas, turned to sculpture, but she returned to painting, stating that it was central to her life.

Deafness and Art

Deafness, which is a widespread condition, can be an early influence toward a career in art (Sonnenstrahl, 2003). It may happen when deaf children use art as a means of communication with their hearing parents as it did with John Lewis Clarke, Ann Silver, and Harry R. Williams. When John Lewis Clarke (American, 1881–1970) was three, he became deaf from scarlet fever. As a boy who was unable to speak, he used clay from the Montana riverbanks near his home to sculpt animals as a way of telling his parents what he had seen that day. Clarke, who became a sculptor specializing in animals, eventually learned to sign in two languages, his Native American Blackfoot sign language and the ASL (American Sign Language) that he learned in schools for the deaf. Ann Silver (American, b. 1949), who was born deaf, also used art in childhood as a way of communicating with her hearing family. A professional artist, Silver still uses art as communication but now it is to promote deaf culture. Harry R. Williams (American, 1948–91) was eighteen months old when he lost his hearing after a reaction to the antibiotic streptomycin. At age four Williams began drawing to communicate with his hearing parents and as an adult, he became famous in the deaf community for his exquisitely drawn symbolist paintings.

Perhaps the best-known artist with a hearing problem is Francisco Goya (Spanish, 1746–1828, also known as Francisco de Goya y Lucientes). In 1792 Goya lost his hearing after a severe illness that kept him incapacitated for months. Goya's precise diagnosis is unknown but after becoming deaf his art transformed and his production increased. Goya began his career as a painter of colorful canvases with scenes of pleasant pastimes but after losing his hearing his work became darker, more structured, and filled with political and psychological content. After his illness, Goya turned into a romantic painter and became a precursor of modern art.

Accidents and Their Legacy in Art

Creativity that starts during convalescence from serious accidents may begin a career in art as it did for David Cox and Frank Day. David Cox (English, 1783–1859) was a blacksmith who broke a leg and started drawing during his recovery. Unable to return to the forge Cox studied painting. He became very successful, exhibiting at the Royal Academy and writing books on art. Frank Leverall Day (American, 1902–76) was a migrant agricultural worker when a farm accident in 1959 broke both of his knees. Day, who began to make art in the hospital rehabilitation program, continued for the next sixteen years until his death. As a Konkow Maidu from California, Day created over two hundred paintings of Native American customs, ceremonies, and legends. Art became a way of preserving his culture for Day, who said, "If I do not do this, all things will be forgotten."

Traffic accidents, a leading cause of disability and death, can inflict severe injury whether people are drivers of cars like Ginny Ruffner or passengers like Howardena Pindell. In 1979 Pindell (American, b. 1943), an art professor, was riding to work at her university with two colleagues when a woman, who had been given pain medication, swerved across the meridian and hit their car. Pindell was trapped in the back seat, her hips misaligned and unconscious from a concussion. In response to the trauma, Pindell said, "My work changed drastically." She went from abstract painting to autobiographical imagery featuring a slave ship to acknowledge her African-American heritage. While the hip injury healed, Pindell still has neurological problems. Although she cannot see all the objects in her visual field, Pindell says she now can focus intensely on repetitive tasks and uses this ability to create intricate patterns in her paintings.

Ginny Ruffner (American, b. 1952) describes her near fatal auto accident in 1991 as "five weeks in a coma, five months in the hospital, and five years in a wheelchair." Trying to avoid another car that had cut across both lanes Ruffner lost control of her vehicle, crossed the median, and spun into ongoing traffic where she had a head-on collision with a first car and then was hit by a second one. In addition to great physical damage, Ruffner suffered a shearing brain injury and her doctors did not think she would live. Yet despite paralysis of her left side that included her drawing hand, double vision, spasms, and a seeming total loss of memory, Ruffner survived. When friends and family brought images of her work, Ruffner began to retrieve memories of her art and started to draw with her right hand. She said, "I knew I would make art again" that making art "was what brought me back." Ruffner now creates by making drawings and supervising assistants who build the finished sculpture. In addition to her previous medium of glass Ruffner has expanded her work to include metal work and book design.

Working With Quadriplegia

Auto accidents can also result in quadriplegia as they did for Ernie Pepion and John Callahan. Yet after being injured both men changed their lifestyles, went to college, and became artists. Ernie Pepion (Eewokso, American, 1943–2005), who worked from a motorized wheelchair with a hand and forearm brace to support his right hand, said, "I am an artist, Blackfeet Indian, and am

physically disabled.” Pepion used his paintings as political/psychological statements to counteract prejudice against quadriplegia and people of color. John Callahan (American, 1951–2010), who was one of America’s leading cartoonists, was also an author, filmmaker, and a role model for other disabled people. Callahan drew by sitting in a motorized wheelchair with a tablet on his lap using his left hand to brace his right.

Sports accidents are another cause of quadriplegia. Cindy Bernhardt (American, b. 1963) was a freshman in college when she was injured in a gymnastics accident and Trevor Wells (English, b. 1956) was an apprentice carpenter age twenty-one when he was injured playing rugby (Alexander, 2005). Completely unable to use their hands, they started making art in hospital rehabilitation programs and went on to have success as painters by holding brushes in their mouths.

When a blood clot lodged in his spine at age 47, Chuck Close (American, b. 1940) became quadriplegic. With very limited movement in his arms and legs, Close paints while sitting in a wheelchair with braces on his legs and a Velcro brush holder attached to his wrist. Two years before the illness Close, who had painted in black and white, began experimenting with color. After the incident his palette expanded, and he has become a colorist. A disciplined worker who paints steadily, Close states that “Every day when I roll out of my studio and look over my shoulder, I say ‘That’s what I did today.’”

Multiple Transforming Illnesses

While Frida Kahlo, Henry Ossawa Tanner, Nell Blaine, Itchiku Kubota, Chuck Close, Lawrence Alma-Tadema, and Odilon Redon all had more than transforming illness, few individuals have had their lives and art as affected by incidents of poor health as Henri Matisse (French, 1869–1954). He had five transforming illnesses. Matisse’s first transforming illness came at age twenty when intestinal problems he had since childhood flared into an acute attack. Forced to recuperate for months, and hoping that creativity might help his boredom, Matisse asked for art supplies. Upon receiving them from his mother he said, “The moment I had this box of colors in my hands, I had the feeling that my life was there.” When Matisse was in his late forties, bronchitis, his second transforming illness, forced him to move to the south of France. The beautiful colors of the Mediterranean brightened his palette and he became a great colorist.

Intestinal cancer at age seventy was Matisse’s third transforming illness. After an operation that went poorly, Matisse became an invalid for the rest of his life. Unwilling to stop working, he started drawing from his bed and then cut out pieces of colored paper while working in a wheelchair. Compositions made of colorful cut paper became a main form of expression for Matisse and include some of his best work. His fourth transforming illness was a gallbladder condition that came soon after the intestinal surgery. Refusing another operation, Matisse sublimated his pain by making book illustrations. The fifth transforming illness came in 1942 when Matisse’s poor health required a nurse. The young woman who was his nurse became a nun and asked him to design a church. Matisse was eighty-four when he finished the *Chapel of the Rosary* and said, “I consider it to be my masterpiece.” The courage and determination of Matisse and other artists to face hardship with creativity indicates the transforming illness is a widespread phenomenon and fundamental to the human condition.

The Therapeutic Action of Art

In 2004 Mihaly Csikszentmihalyi gave a TED talk revealing the genesis of his long-term interest in the subject of creativity. He attributed its beginning to his childhood in war torn Europe when he observed that while most of the adults around him were devastated by World War II, some managed to keep a positive attitude and somehow transcend the tragedy that they were exposed to. Eventually, he concluded that it was engagement in creative endeavors which provided people with meaning and thus helped them cope with the difficulties and tragedies of life.

Definitions of creativity abound; they are varied and complex. The focus in this chapter is limited to artistic creativity as a form of self-expression which holds the potential to promote healing in the wake of traumatic experience. In this context, creativity is not defined by the level of talent or skill of the creator, or the quality of the final product, or its value to society. The emphasis here is on creativity as a potential that exists in all of us, a universal potential which can be manifested when facing a challenging situation and striving to master it. In this context, creativity can be an attitude, an idea, an act, or a product.

The term *trauma*, like the word creativity, is defined broadly here. It is conceptualized as an experience or event falling on a continuum ranging from the inevitable losses that are part of the human condition, to the other extreme – exposure to exceptionally violent and catastrophic events outside of common human experience. Trauma is viewed from a contemporary psychoanalytic perspective and is defined by the experience of the survivor, whether consciously registered or not. Regardless of its specific nature, trauma involves a highly stressful situation that leaves the person emotionally, cognitively, and physically overwhelmed and feeling helpless and vulnerable.

The central thesis of this entry is that creative action is one of the most effective ways of coping with trauma and its aftereffects. Art can provide opportunities to repair what has been shattered by events that have overwhelmed individuals and rendered them helpless. It is in art, through its various metaphors and symbolic disguises, that sorrow is given shape and meaning. By expressing the pain, the artist externalizes it, fashions a container for it, and invites others to become witnesses to his/her suffering. Trauma-art facilitates mourning, it restores continuity and connection, and helps to master the internal chaos that follows in the aftermath of tragedy.

What is it about artistic self-expression which facilitates the working through of traumatic experience? What is the therapeutic action of art, in all its forms, whether writing, poetry, painting, drawing, music, dance, or any other art form? The creative transformations of trauma have been explored in psychology and psychoanalysis for many years by scholars from various theoretical perspectives. The answer to what is the therapeutic or beneficial function of art largely depends on one's theoretical orientation.

For instance, when Sigmund Freud wrote about art and the artist (1908/1959), he approached the subject from an instinct based drive theory model. Within that framework, he developed the concept of *sublimation*, a type of defense mechanism which involves the transformation of unacceptable impulses into socially acceptable actions. Ernst Kris (1952), using the same energy paradigm, extended and elaborated the concept of sublimation. He considered creativity to be one of the organizational functions of the ego and maintained that although the source of inspiration was regressive, the artist has a unique capacity for controlled regression to primary process. For this special ability, Kris coined the phrase "*regression in the service of the ego*." It is noteworthy, that these early formulations of creativity were framed in pathologizing terms like "regression" or as defenses against socially unacceptable impulses. Some of Freud's contemporaries, however, among them Carl Jung and Otto Rank, while still committed to the notion of primary process and the workings of the unconscious, moved away from the conception of art as a mechanism of defense, focusing instead on its potential for self-actualization.

Of those who early on recognized the healing potential of art, Jung's work on creativity stands out above all others, perhaps because it derives from his personal experience with internal demons, which he courageously shared with the world. While others were writing about healing through creative action from a theoretical position, Jung was a living example of it. Whereas some may find many of his metaphysical ideas somewhat archaic and experience-distant, his descriptions of his journey into his own psyche is vibrant and enlightening. For much of his life, Jung kept detailed daily journals filled with self-observations, random thoughts, dreams, visions and spiritual experiences.

Eventually in midlife he transferred the contents of these journals into an ornate volume bound in red leather known as *the Red Book* (Jung, 2009). This book provides an intimate look at the creative process born of trauma resulting in an artistic product with the potential to heal its creator. Jung's early history had been marked by traumatic disruptions of the tie with his mother, and according to Winnicott (1964), he suffered from childhood schizophrenia. In adult life, Jung experienced several breakdowns, one of which he documented in *the Red Book*. Through words and visual images, the book vividly describes and graphically illustrates, the intrusive images that he experienced, which in his words: "burst forth from the unconscious and flooded me like an enigmatic stream and threatened to break me" (Epstein, 2009).

Jung believed that what kept him from a state of madness was his self-analysis. He set out on an extensive and intense spiritual expedition into his inner life and the depths of his soul. Using his powerful intellect, his fertile imagination, and his considerable artistic talents, he created a world in which the disparate aspects of his self could be encountered and worked-through. For this endeavor, he developed a technique which he called "active imagination." This technique, which was a kind of meditation or visualization or hypnotic state, was conceptualized as a voluntary confrontation with the unconscious. After inducing an altered state, he would focus on what surfaced, concentrating on a single image or event and imagining himself into it. The images and dreams which emerged during these active imagination sessions, were then carefully recorded in writing or drawn or painted into his journals and a narrative was created around them. The insights which emerged as Jung practiced these techniques on himself were then generalized to others and became the template for his understanding of creativity and the creative process.

Jung's ideas about the creative process are compatible with contemporary psychoanalytic thinking which identifies creativity as a prime example of the human striving for growth. Although the notion of sublimation continues to be found in current literature, the predominant view emphasizes the transformational and restorative capacity of the creative experience. The shift from a position of compensation for what is lacking, to one of transcendence, has opened a window into the creative process as it attempts to deal with the traumatized and vulnerable self.

Theoreticians interested in the relationship between trauma and creativity have speculated about the nature of the healing process and how creative action plays a role in the transformation of despair and psychic pain. The sense of helplessness which traumatic events evoke, seems to cry out for actions that restore a sense of power to the victim. When the artist/victim finds a way to express the pain through words or actions that can be shared with others, he/she achieves some sense of mastery and connection. Rose (1987), who has written extensively on the subject of art and trauma, proposed that "both creative and clinical processes follow the fundamental psychic principle of attempting to master passively experienced trauma by active repetition" (p. 44). According to Rose, creative work externalizes inner processes and connects the person more intimately to the outside world. What begins as the task of mastering one's personal past for the creative artist becomes a process of externalizing and transcending it.

Rose's observation that creative and clinical processes share a common psychic principle, helps us to understand more specifically how these processes facilitate healing. Similarly, one can better understand the therapeutic relationship between art and trauma when one notes that they have another significant point of connection. The thesis of this entry is that the dissociative process is another link between traumatic experience and its artistic expression. It has been known for many years that dissociation is correlated with a history of trauma and is a common coping strategy of trauma survivors. However, the notion that dissociation is a significant aspect of the creative process is a relatively new idea that has not received adequate recognition. The following section will discuss the phenomenon of dissociation and its relationship to both trauma and the creative process.

Dissociation in Art and Trauma

Based on extensive personal and professional experience with both trauma and the arts, the author offers a new theory of the creative process and its potential for healing. The process of creation is seen as a purposeful (although not always conscious) symbolic reenactment of traumatic experiences that facilitates the working through of overpowering affects. This view of the creative process is a twofold one which involves both dissociation and witnessing as its key elements. Dissociation will be discussed in this section, witnessing in the next.

Dissociation is a general mental state which is different from one's ordinary mode of experiencing. It consists of an altered state of consciousness; a temporary change in one's mental state. The concept of dissociation has been prominent in psychology and in psychoanalysis since its first appearance in the work of Pierre Janet in the early 1900s. Since that time, it has generally been viewed in the context of mental illness (See Schizotypy).

Jung, whose model of personality was a dissociative one, was one of the early voices who referred to dissociation in more neutral terms. He viewed dissociation as a part of the normal operations of the psyche, although he acknowledged that in extreme cases it could have pathological manifestations. The technique of active imagination that he developed was a version of the dissociated state that he enlisted in his clinical work.

Historically the relationship between creativity and dissociation has received little attention in psychoanalytic circles, in contrast to the concept of *regression* which has been viewed as integral to the creative process since its introduction into the literature by Kris (1952). Only a handful of theoreticians have recognized the role of dissociation in creativity. One of the early references can be found in Weissman (1968) who used Kris' concept of regression as a springboard for his own ideas about the creative process and posited a dissociative or desynthesizing function, along with an integrative function of the ego. While he acknowledged the significant role of dissociation in creativity, his interpretation was framed in the context of drive theory and ego psychology, in contrast to the one offered here, which is grounded in the contemporary relational paradigm.

Among relationalists the prevalent view of dissociation continues to be a pathological one, but in recent years there has been some recognition of the fact that certain common and universal events like daydreaming and meditation and other altered states of consciousness are also examples of nonpathological dissociation, a process which can actually be restorative (Richman, 2014). Bromberg (1998) referred to “*healthy dissociation*” as an adaptive function of the human mind, which allows individual self-states to function optimally “when full immersion in a single reality, a single strong affect and a suspension of one’s self-reflective capacity is exactly what is called for or wished for” (p. 273).

The role of dissociation in the creative process is generally unrecognized in the current literature on creativity, with the exception of Csikszentmihalyi’s extensive writings on the concept of flow. Without specifically using the term *dissociation*, Csikszentmihalyi (1990, 2004) introduced the term *flow*, which perfectly describes an altered state of consciousness, or dissociation. He conceptualizes it as a state of consciousness which is automatic, effortless, yet highly focused. His studies of creative individuals from different disciplines indicate that what they have in common is the capacity to become deeply immersed and involved to the point where they can enter an ecstatic state in which their sense of self seems to disappear. Along with it usually comes a lack of awareness of bodily needs, a distorted sense of time, and a transcendence of normal awareness. When he writes about flow, Csikszentmihalyi does so in the context of positive psychology and his focus is on the inspirational aspects of dissociation (See Flow).

For those who are familiar with the hypnotic state, it is noteworthy that it has many common features with what Csikszentmihalyi calls “flow.” Hypnosis is a type of dissociation characterized by heightened attentiveness, receptivity, intense focal concentration, and diminished peripheral attention. In trance, one is able to temporarily put aside evaluative judgment and rational concerns and allow emotionality and imagination to hold sway. There is a greater openness to internal images and fantasies. Affect is intensified and more accessible, so that when it is used for trauma work, it has the potential to evoke the intense affect associated with the original traumatic event. Hence the power of artistic self-expression in working through and mastering traumatic events (Richman, 2014).

In summary, the dissociative state is here understood as an altered state of consciousness that is essentially neutral and paradoxical in nature. On the one hand, it can function as a defense mechanism, which under traumatic circumstances is subject to involuntary states of cognitive and affective alterations of consciousness; on the other hand, it can be a state of intense engagement which can be enlisted temporarily in the service of the creative process and has the potential to heal the creator, and under certain circumstances, to mend the reader or viewer, as well. Thus, the same dissociative process that is responsible for fragmentation of the self when the individual is beset by trauma, is also responsible for its transcendence at moments of inspiration when the artist is deeply immersed in creative work.

Bearing Witness, Being Witnessed, and Self Witnessing

Equally integral to the process of creation, particularly as it is enlisted for trauma work, is the concept of witnessing. Jorge Bose (2005), a contemporary psychoanalytic thinker, writing about the healing function of art brings together the two elements of dissociation and witnessing.

The function of the work of art, in a reciprocal process between the art object and its maker, in the making and in the performing of it, can then be seen as being able to reassert the ability to find meaning and symbolic form and therewith again to communicate to an other, to have a witness and to also communicate with oneself and with dissociated aspects of self-experience (p. 69).

Bose added a critical component which accounts for the healing potential of art. It is the author’s contention that communicating with another, as well as oneself, and having witnesses for one’s creation, is essential for repair and mending.

The witnessing function happens on a number of levels. First, the artist becomes witness to his/her own traumatic experience. By externalizing what is experienced internally as overwhelming and fragmenting, and by fashioning it into a creative product, the artist brings the traumatic experience into the light of day for a new viewing. This enables reflection and integration of something initially terrifying with no boundaries or definition, to be defined and integrated into a coherent meaningful narrative. Second, by sharing his/her art with others, (readers, audiences, listeners, spectators), the artist creates witnesses for the pain and as a result no longer suffers in isolation. Trauma is an alienating experience which often ruptures connections and interferes with one’s sense of continuity over time. The marker of life “before” and “after” tragic events, is a common designation by trauma victims. Having witnesses can restore lost connections and repair ruptures. Finally, the artist bears witness to disturbing events and memorializes them, as he/she writes about them, or paints them, or composes music to remember tragedies that have transpired.

An example of the integration of the three crucial aspects of witnessing can be seen in the art of Holocaust survivor, Marian Kolodziej, a Polish Catholic who at the age of 17, was imprisoned in Auschwitz in the first transport, after he was caught working for the Polish resistance. Somehow Marian managed to survive the horrors of concentration camp life for the duration of the Second World War, after which he returned to Poland, went to art school, and eventually began a brilliant career as a set and costume designer in theater and film.

Like so many other survivors, he did not speak of his traumatic experiences in the concentration camp until many years later. At the age of 72, after he suffered a severe stroke which resulted in the paralysis of his hands, and limbs, he turned to drawing as a form of rehabilitation and began to address his past trauma through his art. His poignant drawings of scenes which he remembered from

his years in Auschwitz became a way of finally facing old demons and bringing them to the light of day after so many years of remaining hidden. His encounter with death the second time around was the stimulus to ultimately come to terms with the past and to give testimony through his art (Schmidt et al., 2010).

For Kolodziej, as for other survivors, the function of witnessing was essential. It took place on several levels, including bearing witness to the tragedy, being witnessed by those who came to see the exhibition of his work, and bearing witness to himself by facing what he himself had been through – Kolodziej's art enabled all three. He frequently made use of the self-portrait, bringing images of his past and present selves into the same frame and juxtaposing them with one another. Through this technique of the double self-portrait he was able to literally and figuratively bear witness to himself – the current self witnessing the traumatized self and acknowledging its suffering and its triumphs. This appears to be an ingenious and creative way of artistically portraying the psychological phenomenon of *doubling* so familiar to survivors of catastrophic trauma. Most survivors exist in two separate worlds, the world of the trauma experience, and in present time. In his creative way, Marian manages to find a way to symbolically integrate them. In this artistic version of *doubling* there is an opportunity to regain a sense of continuity that had been ruptured by trauma.

This internal "witnessing-other" can be viewed as a kind of Muse (Richman, 2014) that is often conjured up in the process of making art. For the trauma survivor, whose experience has been chaotic and fragmenting, the witness can serve a holding function as well as a validating and integrating one. The imagined witness is conceptualized as a dissociated self-state that serves the crucial function of mirroring, affirming, and validating. When traumatic experience is transformed into a work of art, a poem, a collage, or a photograph, the survivor is able to bear witness to his/her own experience; the final product is an external presence and a memorial to what has been lost. Marian's drawings illustrate how artistic expression can be enlisted in the service of working through a traumatic loss, mourning this loss, and preserving memory. As he recalls scenes from Auschwitz, unformulated experiences of pain and loss are given form.

The roles of dissociation and witnessing in the creative process are complementary and essential. They are the building blocks of the new relational theory of creativity that is offered here. What exists inside as unformulated chaos can be formulated, that is, given shape and meaning and witnessed by self and other. Through the creative process, painful disorganizing and overwhelming affects are shaped into images or ideas that have a substance and a reality and can be validated by others. This process counteracts the tendency toward defensive dissociation, the common legacy of trauma. The creative product exists as evidence of one's experience at a specific moment in time and, as such, it endures the vicissitudes of shifting self-states thereby facilitating their integration into a coherent and continuous sense of self. Ultimately, it can contribute to a sense of mastery and empower the trauma survivor.

The creative process is often regarded as a solitary activity, but in fact one can make the case that the presence of the other is always implied since most artistic products are meant for an audience – a viewer, a listener or a reader. Even when there is no actual audience present, an image of an external other may exist in the form of a projected other who will react to the creation and to the individual doing the creating. Kris (1952) wrote: "Wherever artistic creation takes place, the idea of a public exists, though the artist may attribute this role only to one real or imaginary person" (p. 60). The response of others, according to Kris, is essential to confirm the artist's belief in his work and to restore a balance that the creative process may have disturbed.

The viewer or reader or listener who witnesses the creative product, potentially benefits as well. Anna Ornstein (2006), a psychoanalyst and survivor of Auschwitz, wrote about artistic transformation of individual suffering and the transformation of traumatic memories into works of art. She maintained that art can serve a vitalizing selfobject function, a narcissistic experience in which the art object functions in the service of the self fostering the experience of continuity, coherence and well-being for the survivor as well as for those who are consumers of the art work.

Ornstein postulated a complex relationship between the work of art and its audience; a shared experiential space between the subjective reality of the viewer/reader/listener and the artist. Within the self psychology theoretical perspective, she understood artistic creativity as an attempt to ward off or repair fragmentation and to facilitate the re-integration of thought, emotion, and perceptions ruptured by trauma.

Orfanos (2014) wrote about the world renowned composer and activist Mikis Theodorakis, whose melodies and compositions evoke powerful emotions in his audiences and listeners: "Theodorakis creates an intimate dialogue between himself and the listener. Composer and audience collaborate to create a memorializing dialogue by way of relational mourning. This dialogue affirms the powerful feelings of loss and death." (p. 276).

Theodorakis, a survivor of torture during World War II and the *junta* years in Greece (1967–74), knew grief from the inside out and helped his people to collectively mourn and memorialize the deep damage done to their country. Orfanos maintained that Theodorakis' compositions integrate powerful words and sorrowful sounds which evoke passion, longing, and loss. The aesthetic structure allows the listener to enter a safe holding environment where these powerful emotions can be experienced and shared.

Enlisting the Creative Process in Psychotherapy

Jung encouraged his patients to use the technique of active imagination, which had been so curative for him, so that they could uncover their own fantasies and then draw and paint the images that emerged in this altered state of consciousness. Some contemporary practitioners who share Jung's view of personality as dissociative in nature, developed similar techniques in their analytic practice. For instance, Robert Bosnak (2003), a Jungian analyst, uses a method of dreamwork to access psychic states that are normally out of consciousness. He induced a hypnagogic state and guides the person to re-enter his/her dream. His goal in using this imaginal work is to let various aspects of self become aware of one another. Similarly, Bromberg (1998) a relational psychoanalyst,

reported that he occasionally used *embodied imagination*, a creative form of working with memories and dreams based on Jung's principles, when he encounters self-states that have been isolated self-protectively through dissociation. He views this aspect of dissociation as 'normal dissociation' – an aspect of the natural hypnoid capacity of the mind that works in the service of creative adaptation (See Dreams and Creativity).

In clinical practice it is sometimes helpful to work with artistic products that patients spontaneously bring into their sessions, such as a poem, a story, or a painting. Working with symbolic material and images, much like dream work, can be gratifying and enlightening; it engages the creator in a way that can often bypass the censor within. Rotenberg's (1988) formulation suggests how this process takes place: "Unarticulated feelings and ideas are externalized and in the process of their articulation (whether in words, or visually in form and color, or in music) the creative work itself is supposed to validate the artist's not fully conscious intentions" (p. 387).

For creative patients who have lived in the shadow of trauma, artistic self-expression is often particularly compelling. The following vignette illustrates therapeutic work with such a patient. "Samantha" was referred by a physician colleague who worked with her child, a 7-year-old with special needs, whose functioning was severely compromised by a condition similar to autism. The child was multiply disabled, had visual issues, was hearing impaired, and had life threatening allergies to countless foods. One of the most dramatic aspects of her condition was her inability to speak. The mysterious disorder did not even have a name, nor could it be explained by a specific diagnosis.

The trauma of living with a severely handicapped child began late in the pregnancy when Samantha was told that the little girl that she was carrying might not survive beyond the first months of life. Samantha's life consisted of countless visits to various medical specialists, many of whom made dire pronouncements about the future of her baby. She had to give up any plans to be a working mother with a gratifying career, because this child required her full commitment. She could not, or would not, leave her in the care of others. The trauma was ongoing and cumulative; she felt trapped and hopeless. With the birth of this child, the couples' lives were changed forever. Fortunately, they had a good solid, affirming relationship, and Samantha's husband was able to financially support the family and provide the numerous services necessitated by the child's medical condition.

Long before the trauma of parenting a child who was so severely compromised, Samantha had experienced depression and anxiety. Born to a highly critical mother who had strong convictions about the ways that children are supposed to look, behave, and think, and a father who was emotionally distant and abusive, Samantha had learned early on to hide her own values, her thoughts, and even her talents. She recounted how as a child she had hidden her art work under her bed so that she could avoid the criticism which she anticipated.

Samantha's intense anxiety, particularly as it related to the transference, was a recurrent theme in her treatment. Despite her strong attachment to the therapist, and her valuing of the psychotherapy process, she consistently experienced a sense of apprehension in anticipation of her sessions. Sometimes her anxiety took the form of losing her voice. As she spoke about upsetting experiences, she suddenly felt her throat closing up and had difficulty speaking. Anticipating a critical reaction, Samantha had learned early in her life, to keep her thoughts and feelings to herself. Besides the fear of external judgments, she was terrified of entering a dark place from which there would be no return. Caught between the need to express herself, and the wish to escape into silence, she struggled in therapy to face her demons and to find her voice.

While speaking was conflicted, writing was not subject to such inhibition. Samantha loved books, and writing was a form of self-expression that came naturally. Within the first year of therapy, she announced that she was joining a writing group. Apparently, she not only loved fiction writing, but had a talent for it. She found the writing group immensely gratifying; it not only enhanced her self-esteem, but it also facilitated a sense of community with like-minded individuals. It helped her bridge the chasm of isolation that surrounded her. Her fellow-students were captivated by her short stories, and the teacher encouraged her to publish some of them. Eventually a couple of her pieces were accepted for publication.

Sometimes, Samantha brought her stories into sessions by mentioning what she was working on. Much the way that we might explore her dreams, we approached her tales as an opportunity to gain deeper insight into her internal experience. What did these metaphors tell us that we did not already know? How did they add to our understanding of her experience? Generally, Samantha would describe her tales, but one day she actually brought in a completed short story which she handed to the therapist with a mixture of trepidation and anticipation.

The story featured a mannequin named Zoe who spend her days and nights in a department store window watching the world go by until one day, when apparently she had outlived her usefulness, she found herself discarded in a garbage dumpster. The story is told from Zoe's perspective as a thinking, feeling, sensing being. She has strong emotions; she feels panic, despair, longing, but to the world, she is a wooden human-like mannequin in a window display. Zoe is witness to the changing seasons and to life going on around her, lovers kissing in front of the display window at night when the store is closed, children watching with wonder, and shoppers imagining themselves in the attractive seasonal outfits on display. Zoe is rescued from the dumpster by the man who is in charge of dressing the mannequins, and it is he who gives her the name Zoe. Samantha's husband has been the rescuer in her life who recognized her specialness many years ago when they were college students. But even this man cannot know the depth of her longings for life and her deep sense of isolation.

The name Zoe (the Greek word for life) so well captures the irony characteristic of many of Samantha's stories. They are filled with parody and paradox; they depict unsettling events and have a powerful and haunting presence. This beautifully written piece captures the experiences that she talked about in therapy – her description of herself as a "people pleaser" in juxtaposition with her inner sense of herself as lifeless and broken; her experience of her mother as an insecure person who is preoccupied with the reactions of others and with superficial concerns like physical appearance and good manners. The therapist wonders if this story, which

she wants to share, is a parody of her mother's expectations – namely, the wish to have a daughter with a perfect body and a frozen smile who shows no uncomfortable emotions and makes no demands, a mannequin-like figure without human flaws. At the same time, the story seems to have multiple meanings, much like a dream, suggesting that Zoe also represents her own child – a pretty girl without speech, who is dependent on the caretaking of others, yet unable to communicate her basic needs, her thoughts, or her feelings.

How does writing her stories help Samantha mend? Through metaphors and images, she faces the traumatic experience from a safe distance. By sharing them with her writing group she allows others into her closely guarded inner world on her own terms. By bringing her poignant stories into her therapy sessions, she invites her therapist to witness her own inner struggle, her longings, and her suffering. "Helplessness and isolation are the core experiences of psychological trauma. Empowerment and reconnection are the core experiences of recovery." (Herman, 1992, p. 197).

Creative self-expression provides an opportunity to mourn, to memorialize, to find meaning, and to regain some sense of continuity and connection. Through emotional engagement and creative action, passively experienced trauma can be mastered and ultimately mended. From the tragedy of trauma, through her imaginative stories, Samantha constructed something of value that could be communicated, recognized, and witnessed and has the potential to restore connections ruptured by trauma. For Samantha, as for so many trauma survivors, the creative act is both a source, and a sign of vitality and empowerment.

The Unconscious in Creativity	677
The Nonconscious and Conscious in Creativity	678
References	679

There is a long-standing belief in the unconscious wellspring of creativity. Invoked more frequently in connection with creativity than with almost any other human action or experience, the unconscious is considered responsible for mysterious bolts from the blue, flashes of insight, waking from sleep with ideas already formed, and energy-releasing altered states of consciousness. Also, creative writings and works of art seem perfused with unconscious content such as Oedipus complexes, anima and animus, or sexual and aggressive symbolism. So ingrained is the idea that creativity arises from unconscious sources that investigators who present evidence for conscious factors do so at their peril; they run the risk of being rejected out of hand by both professionals and laity.

The belief in the unconscious roots of creativity is tenacious and misleading. Because creativity is unconscious, the adherents often also say, it cannot be explained or adequately understood. Moreover, this belief is closely allied to allegations about a connection between creativity and madness. Nietzsche's concept of the creative artist's Dionysian frenzy, for example, anticipates modern constructions of unconscious influences and emphasizes an extreme irrationality of the creative mind. These ideas, in fact, have a long and almost hallowed history. They go back to the philosopher Plato, who laid their groundwork in the following remarks to the poet Ion:

For the poet is a light and winged and holy thing, and there is no invention in him until he has been inspired and is out of his senses and the mind is no longer in him; when he has not attained to this state, he is powerless and is unable to utter his oracles. Many are the noble words in which poets speak concerning the actions of men; but like yourself [Ion] when speaking about Homer, they do not speak of them by any rules of art: they are simply inspired to utter that to which the Muse impels them, and that only; and when inspired, one of them will make dithyrambs, another hymns of praise, another choral strains, another epic or iambic verses-and he who is good at one is not good at any other kind of verse: for not by art does the poet sing, but by power divine. Had he learned by rules of art, he would have known how to speak not of one theme only, but of all; and therefore God takes away the minds of poets, and uses them as his ministers, as he also uses diviners and holy prophets, in order that we who hear them may know them to be speaking not of themselves who utter these priceless words in a state of unconsciousness, but that God himself is the speaker, and that through them is conversing with us. (Plato, 1924a)

This does not mean that in this passage Plato formulated a concept of an unconscious or that he considered the roots of creativity to lie in some particular aspect of the human mind. On the contrary, he clearly considered creativity to be supernatural or divine in origin and, in another place, stated explicitly that the creative artist's performance was the result of "divine madness." (Plato, 1924b) When performing creatively, the artist's own senses were not directly responsible for the product, and consequently the creative process was a matter of being out of one's mind and bereft of one's senses. Such emphasis on the seemingly possessed aspect of creative activity has been a basis for a long tradition citing both madness and supra-human or external sources for creativity. It has, on the one hand, continued and fostered the classical idea of inspiration by the muse, and on the other, it has today culminated in a psychological emphasis on the unconscious aspect of the mind: rather than ideas being inspired by a source outside the creator himself, they have been located within the creator as another aspect of his mind. Although the idea of creativity arising from the unconscious is not the same as Plato's madness notion, it raises many problems. The modern concept of the unconscious is primarily associated with psychoanalysis and Sigmund Freud. Although Freud actually did not originate the concept-others such as [Eduard von Hartmann \(1869\)](#) proposed it earlier-he was the first to develop a full and systematic theoretical account. Other theorists, notably [Carl Jung \(1966\)](#), also attempted a systematic description of unconscious functioning called the "Collective Unconscious", denying certain aspects of Freud's concept and adding cultural, historical, and other features. Although Jung's concept of the collective unconscious has had a prominent place in some modern theories of creativity, it would not be contributory here to go into a recounting and assessment of the differences between Freud's and Jung's theories of unconscious functioning. As the major

thrust of the matter is similar for both, I shall focus on the Freudian unconscious and only touch on similarities and differences from the Jungian.

Freud and other psychoanalysts fostered the idea that the unconscious and its operant primary process thinking (non-logical nor reality-oriented) plays a significant role in creativity. Turning to great works of art in order to corroborate findings about psychological processes derived from work with patients, psychoanalysts have long been interested in apparent manifestations of the unconscious and the primary process in works of literature and visual art. In his initial presentation of his cornerstone concept of the Oedipus complex, Freud turned for illustration and support to Shakespeare's great play *Hamlet*. Citing Hamlet's inability to act against his uncle-stepfather, together with the intense relationship between Hamlet and his mother, Gertrude, Freud proposed that unconscious incestuous feelings toward Gertrude and murderous feelings toward his real father could explain Hamlet's doubt and torment. After this and other artistic analyses by Freud, numerous other psychoanalysts have attempted to describe myriad instances of unconscious phenomena in works of art. Because of the seeming universality of these instances, creative artists were alleged to be particularly sensitive to their own unconscious processes, and these processes were considered to play a critical role in artistic creation. Artists' own testimonies have also strengthened these considerations. Repeatedly, artists of all types report that they cannot trace the steps in their achievement of outstanding ideas and that such ideas seem to intrude into their awareness without warning or preparation. In many cases, important ideas are said to arise when the artist is not directly working on a creative task but rather while he is relaxing or occupied with something else. In effect, therefore, the Platonic idea of possession by an external factor has been changed to a factor that is external to awareness.

Here, however, there needs to be a caution and a clarification regarding a distinction between the unconscious and the not-conscious. If something is simply described as outside of awareness or not conscious, it is only a negative factor. Saying "no," negating, or canceling out produces broad categories, and describing someone or something as "not tall" or "not hot" merely eliminates a characteristic rather than sharpening or clarifying the description. Although we often use negations as though they were opposites, "not tall" is not synonymous with short, and "not hot" is not equivalent to cold. The negatives of tall and hot include a very large range of height and temperature. Failure to recognize these differences has caused problems with respect to the idea and term "unconscious". It is used both to mean an opposite of consciousness and (together with the other old and misused term, "subconscious") as a negative form roughly equivalent to not-conscious or nonconscious. With respect to creativity and mental illness, lack of clarity about the distinction has caused confusion and misconceptions.

The Unconscious in Creativity

The Freudian definition of the unconscious does not only signify the negative of consciousness, it has specific contents and characteristics. Intrinsic to Freud's psychodynamic point of view is a definitely formulated and therefore positively defined unconscious, an unconscious that is *opposite* to the conscious. Freud's unconscious consists of elements derived from the individual's past which are kept out of awareness for a reason. These elements, designated as drives, wishes, memories, and affects, remain unconscious to the individual himself because they are unacceptable, either personally or socially, and therefore cannot be tolerated in consciousness. They are kept unconscious by the defense mechanism called "repression", an active psychological process or barrier.

Also, elements in the unconscious have a diffuse and controlling effect by virtue of being kept out of awareness. These elements exert a consistent and potentially broad effect on conscious thought and behavior precisely because they actively remain unconscious. Once an element becomes conscious—once its form and substance are known—then it can be changed and modified by intentional control. When unacceptable personal memories, wishes, and affects are kept out of awareness or repressed, they still have force and influence, but they exert an involuntary effect. And the more strongly they are prevented from coming to awareness, the more broad and diffuse is their effect. Strongly repressed unconscious drives, for instance, tend to influence all conscious thought and behavior. Although the matter is somewhat different with respect to the Jungian collective unconscious, the contents and themes of this type of unconscious are derived from the past, too, and they also exert a controlling effect on individual consciousness.

Now, if this type of unconscious were fully responsible for creativity, as many theorists contend, what would that really mean? What would that signify about the nature of creative processes? For one thing, with this type of unconscious and the controlling force of past events as entirely responsible for creative activity, we would have to restrict the definition of creativity severely. True newness, consisting of a complete break with the past, would not be a characteristic, or even a feature, of the creative process or of creations. Creations could not be truly new because they would be the direct product of past and preexisting unconscious factors. A meaningful definition of creativity should include the possibility of human beings producing truly new ideas, theories, artistic styles and forms, or inventions. Consequently, the contention does not work.

A second more telling result of this theory would be that the unacceptable and, in fact, the ordinary and banal contents of the unconscious would be the basis for great works of art and other important human achievements. Although this proposition is not as offensive right off the bat to myself as it is to some, on serious consideration it produces thorny problems. Works of art are decidedly not offensive or unacceptable or banal, and therefore some type of transformation or change would have to occur on the way from the unconscious to the final product. Rather than the unconscious, the particular transforming factor—whatever it is—would become the real cause of creativity. The biggest problem with accepting this idea of unconscious causes of creativity is the tied-in feature of a broad controlling effect on conscious thought and behavior. For although this control could plausibly account for representation of unconscious factors in the content of an artwork, it could not account for artistic form. A primary function of the Freudian

controlling mechanisms is to conceal unconscious content: they alter and distort unconscious material so that it cannot be recognized in consciousness. But artistic form—the shape, patterns, styles, and compositional features of artworks—has an opposite function: it uncovers and reveals deep meanings and psychological processes. It shows the organization of the feelings and actions of human beings as well as of the sounds and sights of nature. Independence from unconscious control of the processes responsible for form is necessary in order to produce revelation rather than concealment and the lucidity of art rather than obscurity. Also, a broadly controlling unconscious force could not produce intrinsically important unities in art, but, because the unconscious is essentially disunified, it would result in disunity or monotony.

Although Jung's collective unconscious is not necessarily a repository of unacceptable affects, drives, and memories, there are similar problems with that formulation. Characteristic themes of the collective unconscious such as the wise old man, the great uroboric or unisexual mother, and the birth of the hero, must also be transformed or changed to have a creative effect. According to Jung, these themes have been transmitted throughout history and are embedded in the past of particular racial and cultural groups or of the human race as a whole. He says the artist uses unconscious "autonomous complexes" to transform these themes into art. (Jung, 1996) This formulation, unfortunately, is redundant and circular and will not do. According to this, autonomous unconscious factors produce both *autonomous* form and content in art.

Despite all these difficulties, there is something to be said for the theories. Aspects of these positively defined types of unconscious functioning, Freudian and Jungian, must play some role in artistic creative production. Ordinary conscious thinking is too stepwise, too free of affect and emotion, and too focused on the natural world and on things as they are to provide the kind of remote and unusual connections and penetrating affective experiences characteristic of art. Emotion-laden operations of the Freudian unconscious which link childhood and adult thoughts and experiences together, infuse feeling, and produce constant shifts in thinking without regard to specific goals play important roles in various phases of the creative process. Also, there is little doubt that artists' unconscious conflicts (and perhaps also the contents of the collective unconscious) determine preoccupations with recurrent themes—although these do not comprise creative transformations. All types of artists return over and over again to themes having the basic structure of some unconscious element, be it the Oedipus complex, bisexuality, castration, reunification with a mothering or fathering figure, or the themes of the collective unconscious. The Oedipus complex, for instance, was not only the concern of Sophocles and Shakespeare, but more recent writers such as Nathaniel Hawthorne, Herman Melville, Eugene O'Neill, Edgar Allan Poe, Samuel Butler, Fyodor Dostoyevsky, Arthur Miller, Tennessee Williams, Harold Pinter, Edward Albee, and Samuel Beckett show definite preoccupation with various aspects of this theme, as do other types of artists as well.

The Nonconscious and Conscious in Creativity

The other type of unconscious functioning is the one that is designated simply as nonconscious. Neural scientists such as Walter B. Cannon (1932) and Charles S. Sherrington (1906) have both argued extensively that creative ideas arise from the nonconscious portion of the mind. Also, Csikszentmihalyi (1996) has proposed that creativity results from what he calls "flow," a state of fully devoted attention and thinking that includes application of nonconscious processes. Unfortunately, the concept of the nonconscious is, as I said, a negative one and is therefore very broad. Proposing a nonconscious mind without any specific attributes like those described by Freud and Jung has only increased the mystery. Discovery of the specific homospatial, janusian and sep-con articulation processes in creativity as described in these volumes, however, does help to solve this problem directly. None of these processes appears directly in awareness, and none of them arises directly from either the Freudian or the Jungian unconscious. None follows the patterns of ordinary stepwise or productive thinking.

With either or all three of these processes, creators are only consciously aware of the products of their thinking. Only the resulting metaphor, characterization, plot idea, visual image, musical phrase, or theoretical formulation appears in consciousness, not the structural features of these processes such as searching for opposites (janusian), superimposing mental images (homospatial) or separating with connecting (sep-con articulation). Because the creators are not aware (and do not need to be aware) of the structure of their thinking and seldom if ever retrace particular thought sequences leading to creative ideas, the ideas seem to them to result from factors out of their control. Because creative persons have intentionally not distracted or hampered themselves in order to focus on, or become aware of, the detailed nature of their thinking, they have never described these processes in their own writings and testimonies about creativity. Only through extensive and painstaking cooperative interviewing and sequence reconstruction together with observation and experimentation have the processes been revealed to me.

The structural features of the janusian, homospatial and sep-con articulation processes account in part for the numerous reports—adding to and abetting a virtual mystique of unconscious creativity—of something coming from out of awareness. In the case of the janusian process, there is a leap of thought in which the multiple opposites or antitheses are brought together at once. Ideas, images, or propositions traditionally considered valid or real are juxtaposed with their polar opposite or opposites; the coming together of such widely disparate elements produces a feeling and experience of something coming out of nowhere. Because the polar opposite has not been seriously entertained previously to be true or meaningful—sometimes not even to exist at all—it is held at the periphery of consciousness. Bringing it together with an idea that is in the focus of attention produces a sense of sudden insight or a leap of thought.

In Albert Einstein's development of the general theory of relativity (Rothenberg, 2015) and described here in the chapter on janusian, homospatial and sep-con articulation), for example, he had considered all the characteristics of gravitation and motion

prior to formulating the key step. He had pondered moving objects, speed, acceleration, and especially the motion of magnets in an electrical field. Rest, the opposite of motion, was the limiting condition at the fringes of the matter until he brought rest and motion together in an image of a person falling from the roof of a house-at rest within his fall. And he described this idea as a thought that came to him while he was working on an essay-he was focused only on the new understanding he had achieved, not on how he had achieved it. Certainly aware that the idea seemed contradictory-in the report I cited elsewhere here- he carefully took up each apparently discordant detail-he was nevertheless moved by his thought. The experience of extreme disparity, the turning around of what was previously believed to be totally untrue or contradictory, is what accounts for the strong feelings of suddenness and strangeness and, in many cases, the sense of outside influence.

The scientist Edwin McMillan also spoke in a research interview (Rothenberg, 2015) of a sudden realization in his discovery of the principle of phase stability. He thought of a particle being out of phase and conceived that it shifted to the "opposite sense". This idea was the breakthrough that led to his recognition of constantly oscillating particles that were in a stable state. Going over the sequence in his thinking several times in order to be sure I had made no mistake in interpretation, I asked him whether he knew that he had conceived of an opposite direction and of simultaneously opposite energy levels. Acknowledging retrospectively that these were his conceptions at the time, he then went on to elaborate on the product of his thinking-the actual phase stability principle he had discovered. In response to further questions, he also made absolutely clear that he was fully conscious and rational at the moment he developed the idea but thought about the content rather than the way in which he had achieved it.

Similarly, with poetry, Pulitzer prize winner James Merrill, whose initial idea for a poem had been that horses are animals who "renounce their own kind in order to live our lives and did not, in a research interview, initially comment on the oppositional characteristics of this thought (Rothenberg, 1979). He had been reading a poem about men and horses written by another poet when he developed the formulation. When I then pointed out the simultaneous opposition in the structure, he completely agreed that it was there and, like McMillan, went on to elaborate on extensions of his conception. Animals, he said, were often more gentle than human beings, and humans often behaved in what were considered "bestial" ways. At the moment of developing his janusian idea about horses for a particular poem, he had not stopped to think about the oppositional structure of his thinking. Appropriately, he was only intrigued by the poetic notion itself.

Creative thinking is nonconscious in this respect primarily. In each case, creators are not generally aware of the specific structural features of the unusual modes of thought which they use in producing a creation. These types of thinking occur, however, when they are fully conscious and in possession of their senses. Neither dreaming nor in a special altered state of consciousness in which unconscious material becomes available, they are not engaged in "regression in the service of the ego." (Kris, 1952) According to that theoretical formulation, unconscious processes erupt into consciousness and, in an unexplained and mysterious way, are controlled by the ego for creative purposes. Instead, the creator characteristically tends to formulate simultaneous oppositions, superimpositions and connection/separations in the creative process without paying attention to how he does so.

The overemphasis on the unconscious, a virtual mystique and its related idea of possession, is therefore a mistake. But that is not the complete story. All conscious thought is in some way influenced by unconscious processes, and janusian, homospatial and sep-con articulation conscious types are not exceptions. For instance, there are often unconscious factors influencing a creative person's focus on a particular task, his or her choice of a particular set of opposites, or the elements superimposed in the homospatial conception or the life connections in his formulations. At times, these particulars may be derived from unconscious conflicts. Although the relationship of janusian, homospatial and sep-con articulation processes to unconscious material is primarily a separate and variable one, unconscious factors and content do appear in creative works, especially artistic ones. In such cases, aspects of the structure of these specific creative processes may be co-ordinate with unconscious dreaming factors and they therefore may to some extent facilitate the appearance of unconscious material in all types of art. I have described (Rothenberg, 1979) this factor as "the mirror image (reversal) of dreaming." The creative processes, because of their psychic structure, reverse aspects of dream thought and they thereby facilitate or unearth some unconscious factors and content. The janusian process involving opposites applies the defense mechanism of negation which suppresses and reflectingly focuses on unconscious content and produces the interchangeability of opposites in dreams; the homospatial process involving spatial superimpositions applies and reverses the dream mechanisms of condensation and compromise formation; and the sep-con articulation process applies and reverses the dream mechanism of displacement.

To come full circle, Plato's description of the matter was not really so far off the mark. Only his conclusions regarding madness and the tradition he fostered, which emphasize a source of creativity completely external to consciousness, are found wanting. The reason the creator is unaware of the specific factors accounting for his skill or art is that he appropriately does not think of the particular structural qualities of the thought processes he uses in producing his creations. They are part of that diffusely negative nonconscious aspect of his mental functioning, and to some degree, they are derived from the specific and positive unconscious defined first by Freud. The creator is, however, neither out of his mind nor bereft of his senses. He is a more sensitive and flexible thinker than the rest of us and is capable of using thought processes and blending modes of thought in unusual and exciting ways.

Utah Conferences

In the 1950s, the National Science Foundation (NSF) sponsored a conference series about the identification of creative talent in science organized by Calvin W. Taylor as the principal investigator and supported by the University of Utah. Three different conferences, titled, *Research Conference on the Identification of Creative Scientific Talent*, were held in Brighton, Utah. The first was organized in 1955 and followed on a biennial basis in 1957 and 1959. The idea for a creativity conference arose from discussions with Harry Kelly and Bowen Dees from the NSF, and the key figures in educational research, such as J. P. Guilford, Benjamin S. Bloom, and Donald W. Taylor, served as the conference organizing committee members. All the presentations and question–response sessions were recorded; and later, transcriptions were published by the University of Utah.

In his talk, Bowen Dees from NSF explained the reasons the conference was supported by the NSF. The NSF was “intensely and continually interested in the question of finding and nurturing those individuals who possess the potentiality for creative accomplishments in science.” As a relatively new institution, the NSF was offering research grants and fellowship programs for researchers in science. One of their motivations was to identify young scientists with high creative potential for their fellowship programs. The NSF also aimed to lead the transformation of administrative or environmental conditions in such a way that they became conducive to scientific outcome in research institutions. The conference encouraged researchers to produce research proposal(s) to expand efforts in identifying creative talent. In an initial document, the NSF documented its main concerns about research in creativity in science. Their primary questions were:

- *What distinguishes a highly original scientific investigator from an apparently equally intelligent scientific contemporary who simply develops and analyzes the ideas of others?*
- *How can the term creativity in science be defined meaningfully?*
- *Is it possible to develop measures of potential for creativity in science and if so, at what stage in an individual's development can such measures be applied?*
- *What additional research is needed in this field?*

It is remarkable that creativity received attention by the NSF and outstanding researchers in a relatively early period. Sir Francis Galton's *Hereditary Genius* (1869) was a pioneer study in creativity research history. However, before the 1950s creativity was primarily associated with intelligence and usually considered in the context of giftedness. The field “creativity research” emerged and was embraced by researchers after J. P. Guilford's seminal speech on creativity at the American Psychological Association convention in 1950. He highlighted that intelligence is not enough to explain certain behaviors or abilities, and the subjects of creativity and divergent thinking had been neglected by psychologists. Hence, he urged researchers and practitioners in psychology to exert more effort to develop appropriate assessment tools to measure creativity, understand the creative personality, and foster creative ability in schools. The Utah creativity conferences were the result of the momentum in creativity research gained after Guilford's 1950 presidential address.

Another factor making these conferences important is the outstanding researchers from the field of educational psychology including J. P. Guilford, Frank Barron, Morris Stein, and Benjamin Bloom. Below is a list of the some of the important speakers and the titles of their presentations.

1955 Conference

- Myron S. Allen, *The Working Procedures of Creative Scientists*. Technical Service Research, Long Beach, CA.
- Morris I. Stein, *Creativity and/or Success: A Study in Value Conflict*. Department of Psychology, University of Chicago, Chicago, IL.

1959 Conference

- Raymond B. Cattell, *The Personality and Motivation of the Researcher from Measurement of Contemporaries and from Biography*. Laboratory of Personality Assessment, University of Illinois, IL.

- J. W. Getzels and P. W. Jackson, *The Highly Intelligent and the Highly Creative Adolescent: A Summary of Some Research Findings*. University of Chicago, Chicago, IL.
- N. E. Golovin, *The Creative Person in Science*. Advance Research Projects Agency, Department of Defense.
- J. P. Guilford, *Intellectual Resources and Their Values as Seen in Science*. Department of Psychology, University of Southern California, Los Angeles, CA.
- Frank B. Jex, *Negative Validities for Two Different Ingenuity*. University of Utah, Salt Lake City, UT.
- Norman Kaplan, *The Relation of Creativity to Sociological Variables in Research Organizations*. University of Pennsylvania, Philadelphia, PA.
- Thomas S. Kuhn, *The Essential Tension: Tradition and Innovation in Scientific Research*. University of California, Berkeley, CA.
- Sidney J. Parnes and Arnold Meadow, *Development of Individual Creative Talent*. University of Buffalo, NY.
- Anne Roe, *Personal Problems and Science*. Harvard University, MA.
- Thomas B. Sprecher, *A Proposal for Identifying the Meaning of Creativity*. Psychological Service of Pittsburgh, PA.
- Calvin W. Taylor, William R. Smith, and Brewster Ghiselin, *The Creative and Other Contributions of One Sample of Research Scientists*. University of Utah, Salt Lake City, UT.

Beyond the individual presentations, the conferences set up committees to discuss the key issues on the future of creativity research. For instance, at the 1955 conference, aptitude, personality, and criterion committees were formed, and different group of researchers discussed and reported on current issues and future directions. The aptitude committee reported that new tests were needed for the assessment of creativity, and they should be able to measure integrative ability, ideational power, different manifestations of creativity, risk-taking, and decision-making. The group also recommended that new creativity tests should include different formats, such as verbal, nonverbal, possibly other senses, and analogies to create an inclusive assessment procedure. The aptitude committee addressed important principles for collaborative works in creativity research. Some of the issues were discussed in the committee, but the group was not in agreement; thus, they were reported as unresolved. They included the criterion problem in the assessment of creativity, the predictive variance for various levels of creative ability, devising creativity tests for different developmental levels, appropriate methods for analysis of creativity measures, and reliability and validity issues. Finally, the committees listed new areas for future research: creative test performance under different conditions such as the influence of drugs, gender differences, scoring procedures, the development of creativity in early ages, exceptional creativity in early ages and its persistency, group creativity, whether creativity can be learned, and the optimum level of creativity.

The personality committee sought answers to three questions: "What are the psychological characteristics of scientists in general? What are the distinguishing motives that separate creative scientists from uncreative scientists? What can we say about situational factors as they affect scientists in one type of environment as opposed to another?" Following discussions regarding the main questions, the committee had a brainstorming session about the characteristics of scientists. They came up with 24 attributes, such as impulsiveness, abstract thinking, autonomy and tolerance of ambiguity. Then, 24 attributes were clustered around 7 themes:

1. Manipulation of ideas.
2. The general quality of impulse control, repression of affects, isolation, and suppression.
3. Lower social involvement.
4. Autonomy and independence.
5. Tolerance to complexity and ambiguity.
6. A liking for things and a preoccupation with the physical universe.
7. Use of more sophisticated thought processes.

Their discussion indicated that these seven themes are common characteristics of creative scientists, and the level of each theme differentiates creative scientists from their noncreative colleagues. The committee reported that more research is needed to clarify the influence of social climate on creativity, career options for different characteristics such as industry versus academia, and the biological and cultural factors for creativity.

Finally, in the criterion committee, the members discussed a possible criterion measure for assessment of scientific creativity. Among several possibilities, measuring scientists' creative achievements or accomplishments emerged as a viable method. The committee reported that it could be achieved in two ways, one measuring overall achievement in science, and the other assessing a scientist's invention based on expert judges in the field. It was noted that noncreative accomplishments or nonscientific creative productions should be excluded from such assessment.

Relevance to Current Research

The Utah creativity conferences were important because they touched on topics that are still being debated today. For instance, the criterion committee and Joe H. McPherson addressed the criterion problem, referring to a lack of criterion validity in creativity

measures. In the creativity context, measures should predict certain abilities or behaviors. Using scientific creative products and expert judges was proposed by the committee and McPherson, but such suggestions needed to be adapted for other domains; and using judges for creative product evaluation needed further clarification and empirical studies before becoming a viable method.

More recent studies on the Consensual Assessment Technique (CAT), using expert judges for assessment of creativity on products, are in line with the issues discussed at the conferences. However, the definition and level of expertise and subjectivity of CAT are still being discussed in the literature. Measures on creative achievement and ideation, such as the Creative Activities and Accomplishment Checklist (CAAC) and the Runco Ideational Behavior Scale (RIBS), are also the result of the efforts to address the criterion problem in creativity. Another issue is the scope and definition of creativity. Since creativity is a multifaceted phenomenon, there is no consensus on its definition, and it is not likely that a single measure can capture all its components. As a result, there is an ongoing effort to develop a more comprehensive creativity measure/set of measures or improve the existing ones for best assessment practices.

The Utah creativity conferences may imply a paradigm shift in creativity research in the 1950s. As (Csikszentmihalyi 2015) argued, early studies investigating creativity predominantly focused on the concept of genius, which refers to exceptional creativity and intelligence. It was the common approach that creativity could be understood through studying factors in the individual such as cognitive processes, emotions, and motivation. Although the terms creativity and genius are closely related, all creative people are not necessarily geniuses, and not all geniuses produce creative products. Moreover, many social, economic, and cultural factors should be considered to develop a better understanding of creativity. In the presentations and discussions, there was an emphasis on socially recognized and breakthrough scientific productions, and the conferences urged researchers to conduct more studies on social context or the creative climate to develop a creativity-fostering environment for creative production. After the 1950s, there were a growing number of studies about the social psychology of creativity by researchers including Morris Stein, Dean Simonton, and Teresa Amabile.

At the 1955 conference, Raymond Gould from the National Institute of Mental Health talked about the connection between creativity and mental health. He argued that creative abilities and creativity in interpersonal relations may contribute positively to personal mental health. It was and still is a common myth that creativity is associated with psychopathology. Early studies on eminent creators repeatedly concluded that creativity is associated with madness, and such finding led to a negative perspective about creativity. More recent studies, however, show that creativity is a positive trait and connected with personal well-being. Despite the popularity of mad-genius hypothesis, Raymond Gould framed creativity as a strength for personal and community-level mental health. Many other presenters also addressed creativity as an important personal ability to boost creative production in science. Research regarding the use of expressive arts in healing has confirmed the value of creativity in working with individuals with mental health issues.

Conclusion

The Utah research conferences on the identification of creative scientific talent brought together outstanding researchers, psychologists, and psychometricians. They held valuable presentations and discussions on a variety of issues, such as the assessment of creativity, social and cultural factors, creativity and mental health, and the characteristics of creativity. Significant research questions and recommendations resulted from in-depth discussions for the future directions in the field.

As noted above, there seems to have been a nurture/nature paradigm shift in the 1950s, and several discussions and presentations elaborated on creativity and environmental conditions. The social psychology of creativity was, however, relatively new, and the existing research was mostly case studies in scientific institutions. There was a lack of research about environmental conditions for creativity, social-cultural climate, domain differences, and creativity in organizational and school settings. In their presentations, Benjamin Bloom, Lindsey Harmon, and Norman Kaplan emphasized that creativity does not occur in isolation, thus, social and cultural factors should be taken into account. The Utah Conferences inspired further research on these issues, and the publication of important research studies.

Another significant contribution of the conferences was increased understanding of the domain specificity of creativity. In Utah conference series, creativity in science was valued and emerged as a viable research field to improve scientific production and novelty in a competitive global setting. The criterion committee in the 1957 conference suggested that creativity is a complex and multifaceted phenomenon, so separation of different disciplines/domains is necessary to properly assess and evaluate creative potential and production. Presenters, like Guilford, Taylor, and Harmon, shared their thoughts on the characteristics of scientific creativity and their implications for the assessment. Discussions on scientific creativity, of course, opened new possibilities for other domains, such as creativity in interpersonal relations, organizations, entrepreneurship, and educational practices, and significantly contributed to the current discussion of domain specificity issue.

The conferences also touched upon many other issues, such as the intelligence-creativity relation, risk-taking, and the creative process. The in-depth presentations and discussions pioneered creativity research as a distinct and valuable field. The conferences led to an extension of the boundaries of creativity research, opened new directions and possibilities for the future of the field, and have had a lasting effect in the history of creativity research.

Definition of Virtual Reality

Virtual reality, as its name implies, is a combination of the definition of ‘virtual’ and ‘reality’. The word “virtual” is originally defined as things that exist in essence but not in actuality. With the development of information technology, it produces a huge amount of computer-generated information. Currently, the word “virtual” is frequently used to describe things that can be done or seen on a personal computer or a computer network. The word “reality” means actually existed things as opposed to imagination. Combining the two words, the term “virtual reality” refers to the use of computer modeling and simulation to present an environment or offer experience that does not really exist in a physical world.

The Technical Landscape of Virtual Reality

Like many other techniques in history, the earliest technological concept of virtual reality was proposed in science fiction. In 1935, an American science fiction writer Stanley Weinbaum released a science fiction story, *Pygmalion’s Spectacles*. In the story, a professor invents a pair of goggles transporting people into a fictional world in which he could have senses of sight, hearing, taste, smell, and touch. In the middle of the 1950s, a filmmaker Morton Heilig developed the first fully immersive virtual reality system, Sensorama. The machine combines a full color stereoscopic 3D video, an audio, a motional vibrating chair, and smell shots. The Sensorama provides an immerse experience for viewing films, which was thought as the cinema of the future. In 1960s, two engineers in Philco Corporation combined a magnetic motion tracking system with a video screen to develop the first motion-tracking head-mounted display, Headsight. The Headsight was used by the military to observe dangerous situations remotely. However, due to the weak capabilities of graphics processing units of computers at that time, these displays are only connected to cameras and cannot present virtual stimulated scenes generated by computer rendering. Until the middle of the 1960s, Ivan Sutherland, a computer scientist connected head-mount displays to a computer. He and his collaborators developed a head-mounted display (HMD) system, the Sword of Damocles, which allows users to view a virtual environment through HMD and interact with virtual objects (Sutherland, 1968). The Sword of Damocles is known as the first HMD system in history to present “virtual” environments generated by real-time simulation. However, due to heavy weights of virtual reality HMDs, virtual reality systems had not extended beyond laboratory projects for a long time until the middle of the 1980s. In 1984, Jaron Lanier and Thomas Zimmerman founded a company, VPL Research. This company is considered to be the first company to sell commercial virtual reality goggles and gloves to the public. They developed a series of virtual reality software and hardware, which are very close to virtual reality products in a modern sense, such as, an input device, DataGlove, a head-mounted display unit, EyePhone HMD, a 3D sound system, Audio Sphere, a real-time 3D visual rendering engine, Isaac and a visual programming language, Body Electric. These products are very close to modern virtual reality products, creating an integrated system of software and hardware to enable the application of virtual reality.

In addition to HMD, another type of virtual reality system is projection-based virtual reality, which creates a virtual reality experience via 3D projections. In the middle of 1970s, Myron Krueger, an American computer artist, established a virtual reality system defined as the Videoplace. The Videoplace used projectors and video cameras to create an interactive environment. To generate immersive experience, researchers at the Electronic Visualization Laboratory, the University of Illinois, combined multiple projection screens into a cube-like space. The system is named as Cave automatic virtual environment since its space is similar to a prehistoric cave painting. A typical cave system consisted of a cube-shaped room in which the walls, floors or ceilings are projection

screens. A user sits in the cue room watching a virtual environment through a 3D glass. He/she could interact with a virtual environment through input devices such as controller, body gesture or data gloves.

The second component of the virtual reality system is the input device by which a user interacts with a virtual world. Interaction in a 3D virtual environment is much more complicated than that in a conventional 2D display, involving object positioning, rotating, scaling. It is not very convenient to use a keyboard and mouse to manipulate objects in a 3D space. In 1981, Kensington launched a famous trackball mouse that contained a ball held by a socket. User rotated balls to position the cursor and rotate objects on a screen. A trackball mouse has been considered as one of the most efficient input devices for 3D modeling software. In the late 1980s, Colin Ware developed a six-dimensional mouse named bat (Ware and Jessome, 1988). The mouse used a spatial sensor with six degrees of freedom to signal orientation and position relative to a fixed source, which allows positional placement and angular placement. Researchers at Fraunhofer IMK developed a cubic mouse for users to specify three-dimensional coordinates in graphics interfaces (Fröhlich and Plate, 2000). The device includes a cube-shaped box with three perpendicular rods representing X, Y and Z axes in a three-dimensional space. A user pushes and pulls the rods to control positions and orientations of virtual objects in a 3D environment. In 1993, 3Dconnexion, a subsidiary of Logitech launched the first consumer 3D mouse, SpaceMouse, providing a comfortable and natural way to manipulate 3D models. The mouse is still popular today.

In addition, users normally stand or walk around when they interact with a virtual environment. In that case, there is no supporting surface to place a mouse or keyboard. Users have to carry interaction devices in interacting with virtual environments. Therefore, it is essential to design portable interactive devices in a virtual reality system. In early 1980, the Nintendo designed an entertainment system controller, which becomes a classic model of the modern game controller. The controller utilizes the cross-shaped joystick for direction controls and four buttons for menu selection. However, the cross-shaped joystick is not efficient for rapid movements in a 3D space. In 1996, Nintendo added a thumb-operated control stick into the middle of its controller, which allows a player to have 360 degrees of control of locomotion. A year later, Sony released a DualShock analog controller, the first dual analog controller for game consoles. The left stick controls a user's direction and movement and the right stick rotates the view direction of the camera. The combination of two sticks provides a very efficient way for a user to navigate in a 3D space.

In 2001, Microsoft stepped into the video game console business and developed an Xbox controller to compete Sony's PlayStation 2. The design looks similar to DualShock controller, including a cross-shaped joystick and two analog sticks for directional and camera viewpoint control. The layout of buttons is further optimized such as reversing the position of the cross-shaped joystick and the left analog sticks. The Xbox controller has become the gold standard for game controllers after continuous optimization in ergonomics in the last decade. In 2015, HTC Vive implemented the tracking technology to its controller and developed a completely new interactive system. The system consists of a pair of controllers. Each of them is equipped with 24 infrared sensors to detect the positions of the controller. The system allows users to interact and play with virtual worlds by moving or rotating their hands, which is much more intuitive than moving a cursor through a gamepad. Launch of HTC vive started a new era of interaction devices in virtual reality. Other major players in the virtual reality market such as Oculus and Sony followed closely the efforts that developed controllers with a similar technical framework.

Although these controllers provide an efficient way for users to interact with a 3D space, the interaction is still not natural. Moreover, holding controllers for a long time would also cause fatigue no matter how light they are. It is valuable to develop wearable devices for virtual reality applications. Data Glove offers a new way for users to interact with a virtual reality world, which allows users to put down controllers and interact with virtual reality games using their own hands. There are three different technical approaches for gloves: Fabric gloves, thimbles, and exoskeletons. In a fabric glove, flex sensors or optical fiber sensors are implemented into a glove to detect the degree of bending of each finger (McDowall et al., 2000). The movements of fingers collected by gloves are interpreted as input commands by a host computer in a virtual reality system. Given individual differences of hand size and hand shape, it is a very challenge to design adaptable gloves to fit the shape of the hands of an arbitrary user. Instead of covering hands and all fingers, the second type glove, thimbles only use several thimbles attached to a fingertip as sensors. Comparatively, thimble glove fits easily into hands with different sizes and shapes. However, it also raises the challenge to integrate many electronic components into a very light and compact device. The third type of glove is the exoskeleton, which is an articulated structure parallel to fingers on the outside of the hand (Caldwell et al., 1995). The structure could be adjusted to fit a variety of hand sizes and shapes. However, this also leads to a quite heavy and cumbersome mechanical structure, reducing its applicability and effectiveness. Due to these challenges and technical limitations, none of these gloves has won a great commercial success so far. In contrast, a more natural approach for human-computer interaction, vision-based gesture recognition gradually gained the attention of the industry (Moeslund and Granum, 2001; Rautaray and Agrawal, 2015). The system used digital cameras to acquire images of people's gestures and computer vision algorithms to interpret gestures as input signals. Although it cannot provide the same accuracy as data gloves, it meets the requirements of commercial products. They are many products implementing gesture-based recognition technology, such as the Xbox of Microsoft Kinect, SoftKinetic of Sony and Leapmotion.

In some of the virtual reality applications, users are not free to move their hands or bodies. It is important to develop techniques that enable hands-free operation in virtual environments. As humans tend to look at what they are willing to interact with, the human eye gaze is a natural and intuitive way of interacting with environments. Gaze control could be achieved through eye-tracking systems. A modern eye tracker normally uses infrared light to illuminate human eyes and capture reflections through a camera to determine where a person is looking (Tanriverdi and Jacob, 2000). The control system based on eye-tracking has been successfully used to aid people with physical disabilities to manipulate a cursor and click on icons on a screen. Recently developed eye-tracking sensors are sufficient to capture a real-time signal of a viewer's gaze point in high precision and small enough to be integrated into a head-mounted display (HMDs). In 2017, a Japanese company FOVE released the world's first virtual reality

headset with a built-in eye-tracking system, which shows the feasibility of integrating an eye-tracking system into HMDs. The other major players in the virtual reality market, such as Facebook and HTC, get started developing similar eye-tracking head-mounted displays. In 2016, Facebook acquired an Eye Tribe, a startup company which creates the first multi-platform eye-tracking solution for virtual reality applications. The technology is expected to be integrated into future Oculus virtual reality products. HTC has collaborated with a famous eye-tracking company Tobii and applied its eye-tracking technology into the new VIVE Pro Eye headset which has been launched in 2019.

Human speech is another hand-free medium to interact with machines. A voice-user interface (VUI) relies on speech recognition to understand users' spoken commands to enable hands-free interaction. In recent years, the accuracy of speech recognition has been greatly improved by machine learning technology and reached an acceptable level for most people even under certain noisy environments. Thus, VUI has become increasingly popular in intelligent devices, such as mobile phones, automobile's entertainment console, and smart home devices. Many large companies provide application programming interfaces (API) for speech recognition, such as Microsoft Windows Speech Recognition system, Google Cloud Speech APIs, IBM Watson Speech APIs. In 2017, Oculus integrated voice recognition into its HMDs to enable users to easily search and navigate in virtual environments.

Although virtual reality systems have been in development for many years, it is inaccessible for average users due to the high cost and poor user experience of virtual reality system. An HMD could easily cost \$20,000 in ten years ago and a CAVE-like virtual-reality device would even cost millions of dollars. Moreover, due to the limitation of technology in electronic, mechanical and optical engineering, these HMDs were too heavy for users to comfortably wear, resulting in poor user experience. Moreover, the conflicts between visually perceived movement in HMDs and the vestibular system's sense of movement result in motion sickness when a user wears HMDs. Thus, the applications of virtual reality have been mainly developed in the field of military or aerospace which are price-insensitive and have a high tolerance of unsatisfied user experience.

In recent five years, as the cost of virtual reality goes down and the application of virtual reality becomes more mainstream in consumer markets. In 2012, a start-up company Oculus made a huge leap forward for virtual reality. The company created a portable, self-contained HMDs with a weight of around 0.5 kg. The HMD provides a functioning virtual reality system, including two LED displays at a resolution of 1080×1200 , generating 110° field of view for an immersive experience (Desai et al., 2014). The system integrates a portable sensor to track the position of the HMD. Moreover, the system only cost around 300 dollars, which is cheap enough for average consumers to purchase and use at home. As one of the leading companies in virtual reality development, Oculus was purchased by Facebook in 2014 at two billion dollars, which boost the investment in consumer-oriented virtual reality products in the market. Progress of virtual reality technology offers social scientists a cost-effective tool to study human behaviors (Blascovich et al., 2002; Parsons et al., 2017; Zhou et al., 2019).

Virtual Reality and Creativity

Creativity is recognized as the ability to create something new or solve problems in novel ways. Creativity is one of the most precious talents of human beings. Understanding the ways of promoting creativity is important for improving the quality of education. Virtual reality technology could be an effective tool for creativity research and education given its advantage in creating unique virtual environment. First, it is well known that creativity is influenced by environmental factors. Living and playing in a rich environment may nurture the development of human creativity. Virtual reality technology offers a rich, vivid and immersive experience that generates powerful emotion to inspire human creativity. Passig and Eden (2000) found that playing 3D games in virtual reality increases the flexible thinking of disabled children. Hu et al. (2016) used creative thinking instruction such as the application of individualized instruction to facilitate human creative ability and found that using virtual reality could significantly improve the effectiveness of creative thinking instruction.

Second, the development of virtual reality technology offers an opportunity to create a standard and ecologically valid environment for assessing creativity. In virtual environments, stimulus parameters are easily manipulated, which provides convenience to investigate the factors affecting creativity in controllable testing environments. Minas et al. tested whether "openness" of the environment could affect creative thinking. The experiment constructed an open virtual space and closed room with a wall and roof and asked participants to perform brainstorming tasks in the space (Minas et al., 2016). They found that participants demonstrated higher creativity in open environments than that in closed rooms.

Third, virtual reality technology is also changing the way we present creativity. In innovation activities, human beings construct a new world in their minds through a lot of mental thinking and imagination. Virtual reality provides a fast, low-cost way to visualize people's thinking and imagination that could assist people in creative thinking activities. The technology would affect the way of working in creative industries such as advertising, architecture, design, fashion, film, and video. For example, artists could present their work in virtual reality to provide an immersive viewing experience for audiences.

Fourth, virtual reality technology can also be used to simulate some scenes that are difficult to achieve in real life, thus creating novel and different stimuli to improve people's creativity. For instance, using VR technology, Wang et al. (2018) built a scenario where subjects could break through walls to embody the metaphor of "breaking the rules", and found that participants generated more original ideas in the break-wall condition than in the no-wall condition. They also explored the neural correlates of this effect by combining VR and functional near-infrared spectroscopy (fNIRS), and found weaker activations in several brain regions under

the “break-wall” condition, including the frontopolar cortex, the dorsolateral prefrontal cortex, and the somatosensory association cortex (Wang et al., 2019). fNIRS offers high freedom in recording participants’ brain activities in various scenes, and it is compatible with VR equipment, which can better assist VR research.

In summary, virtual reality technology is a medium that is able to induce the experience of “presence” in a computer-generated world, and thus it can be used to simulate various and calculable experience. By designing targeted virtual environments to alter the individual’s experience, virtual reality technology could be a powerful tool for multitudinous research and education.

Introduction

Humans are predominantly visual creatures. In evolutionary terms, the ability to detect and process electromagnetic radiation in the form of visible light is exquisitely adaptive, allowing us to perceive and understand distal aspects of our environment and to plan movements consistent with that reality (Palmer, 1999). Vision is so useful that eyes or eyespots have independently evolved at least 40 times in the history of the animal kingdom, and some 96% of animal species have some form of a complex optical system.

The process of visual perception is essentially one of interpretation. The key problem in perception is to go from the basic detection of a two-dimensional pattern of electromagnetic radiation toward a pragmatic veridical understanding of the environment. Much of the human brain is involved in efficiently processing diverse streams of visual information (including form, color, and motion) in order to establish a unified, stable, and comprehensible percept. While the processing of visual input can occasionally be faulty – witness the susceptibility to optical illusions – for the most part our brains execute perception seamlessly and unconsciously. This is especially impressive given the profound computational challenges of dealing with input that is inherently ambiguous, transient, or incomplete.

In the course of perceiving the visual world, we build up representations of optical or spatial information. These are also useful for tasks that go beyond our immediate needs for understanding and behaving in the local environment, including learning, mental imagery, and creative imagination. Aesthetic domains like visual art are most strongly associated with the creative use of perception, but this is also true of scientific domains.

This chapter discusses visual perception and information processing as they relate to human creativity. First is a description of the structure and functions of visual processing in the eye and brain. Then comes a discussion of how visual perception relates to creativity in a domain-general way, via psychometric efforts to measure visual creativity and studies of insight, imagery, and personality. An exploration of domain-specific aspects of creativity and visual perception follows – mainly in the visual arts, but in several other domains as well. The chapter concludes with some integrative remarks and a brief discussion of future research areas.

Organization of the Human Visual System

Processing Stages

To understand how visual perception relates to creativity, one must understand the basics of how the human visual system is organized. Visual perception proceeds as a sequence of processing stages occurring in different parts of the eye and brain (Palmer, 1999). Initially, light energy enters the eye, focused by the lens onto the inside rear wall of the eyeball, which is lined with millions of light-sensitive cells called photoreceptors. Photoreceptors are divided into two types: color-sensitive cones, which are concentrated in the fovea (the area of the retina corresponding to whatever location in space a person is directly looking at), and rods, which are more sensitive to low levels of light (but not to color) and which are distributed over the entire retina. Incoming photons strike individual photoreceptors, activating them and causing an electrochemical signal to be propagated through several layers of cells. During this

process, information from multiple photoreceptors is combined into doughnut-shaped center-surround receptive fields. Signals from all photoreceptors are eventually gathered together into the optic nerve leading out of the eye, through the subcortical region of the brain called the thalamus, and then to the occipital (rear) lobe of the brain.

Early cortical analysis of the visual signal in the occipital lobe consists of neurons that function as ‘feature detectors.’ These respond preferentially to bars of light in specific orientations. This is useful for identifying areas of discontinuity in the visual field, which typically indicate the edges of objects. After basic feature detection and analysis, visual processing splits into several parallel streams. These include the ventral stream, which passes into the temporal lobe and which performs object recognition, and the dorsal stream, which passes into the parietal lobe and which is involved with the guidance of actions and analysis of objects’ locations. The different streams of processing are eventually pooled into a unitary percept, or interpretation, of the visual world, which forms the basis of understanding and action.

This thumbnail sketch of the main stages and pathways of visual processing is extremely condensed. There are many other aspects of visual processing, including the analysis of motion and color, reciprocal connectivity between early and late stages of processing and between different streams of processing, the integration of information from other senses and toward motor output, and goal-directed executive control over visual and attentional processes. Beyond the psychological mechanisms that are directly used in perception, others act to transform visual or spatial information for other purposes. Component skills along these lines include visualization, mental rotation speed, speed and flexibility of closure, basic perceptual speed, and visual memory. Of these, perhaps only visualization, that is, the imagination of spatial forms and rotation of them in space, can claim evidence of being important for enabling creativity (Palmiero and Srinivasan, 2015), of which more below.

Relevance to Creativity

How do all these varied characteristics of the visual system relate to creativity? Arguably, the computational achievement of vision is itself a creative act, in that it must derive a meaningful interpretation of the world from markedly underdetermined input. However, other structural characteristics of visual processing also impact higher-level creative thinking. For instance, visual processing is sequential, following a logical progression from the pixel-like activation of retinal photoreceptors, to oriented lines, to increasingly complex multi-dimensional representations involving motion, color, texture, object identity and position in space, and potential action. This sequence provides a processing scaffold that is remarkable in its efficiency and unconscious quality – at first glance, features that might seem to work against the generation of novel or creative representations. Indeed, the lack of direct conscious access to early representations constrain how we organize our perception in the first place, and how our perceptual representations might be used in creative thought – see, for instance, a study of artists’ perception by [Perdreau and Cavanagh \(2011\)](#), whose answer to the provocative question of whether artists can see their retinas was a clear ‘no.’

However, perception is not purely a bottom-up (that is, input-driven) reaction to the environment. There are always some top-down guiding effects of context, expectation, knowledge, and assumptions. To some extent, humans can exercise attentional control over how and what we perceive. Executive control can thus significantly impact the synthesis and organization of perceptual representations, which in turn can form the basis for creative imagery, ideation, or production; the same may be said of perceptual processes during altered states of consciousness. Even at the neuroanatomical level, the division of labor evident in many aspects of visual processing – different streams analyzing form versus color versus location versus motion, for instance – can engender creative or aesthetic possibility.

Consider a few examples to drive this point home. One instance involves drawing skill, a critical component of visual artistry. Most people find realistic drawing very difficult. A venerable (but false) explanation for artists’ ability to solve this problem is that they employ an ‘innocent eye’ strategy, achieving accuracy by drawing only what they see, without any interference from their conceptual knowledge. In addressing this issue, [Gombrich \(1960\)](#) noted that the initial two-dimensional retinal image of a three-dimensional world necessarily involves a loss of information, which cannot be perceptually recovered without some top-down, or hypothesis-driven, influence. (This argument applies both to perception and the making of realistic art.) In contrast to this advice to ‘forget what you know’ in order to draw more accurately, Gombrich argued precisely the opposite: knowledge of the structure of appearances should be harnessed to more astutely select the information most critical for perceptual recognition. The multifariousness of visual processing gives artists diverse options in style choice, just as our visual system can be tuned to various perceptual ends based on our goals.

Two additional examples ([Livingstone, 2002](#)) reinforced how artists might use intuitive knowledge of the structure of the visual system to produce creative effects. First, the coy quality of Leonardo da Vinci’s *Mona Lisa* – who appears to smile only when a viewer looks away from her mouth – can arguably be understood in neuroanatomical terms. Specifically, the smile appears least evident at high spatial frequencies, that is, in the local detail we see when directly looking at something. However, the smile is more apparent at low spatial frequencies, that is, in the unfocused blur of our visual periphery when we look away from Mona Lisa’s face. Similarly, the flickering quality some viewers report when looking at Claude Monet’s painting, *Impression: Sunrise*, may be regarded as a consequence of the fact that Monet painted the red sun and blue-gray background in the painting at the same level of luminance, or brightness. Color processing channels in the brain can ‘see’ the sun, but black-and-white form channels in the brain cannot; this discordance in the outputs of the two streams induces a subjective perceptual flickering.

These examples suggest that the complexity and flexibility of the basic functioning of the visual system – including our capacity to generate internal representations via mental imagery – can be exploited to creative or aesthetic ends. The use of visual

imagination, which need not be directly tethered to real-time visual input, increases the creative possibilities of perception-related processes still further.

Domain-General Aspects of Visual Creativity

Theoretical Accounts

Several prominent theoretical accounts in psychology have emphasized the importance of the visual modality for creativity. For instance, [Gardner \(1983\)](#) accounted visual-spatial ability as one of his so-called multiple intelligences (along with mathematical, linguistic, musical, kinesthetic, interpersonal, and intrapersonal abilities). [Feist \(2004\)](#) argued that visual artistry is a fundamental 'domain of mind' that reflects longstanding evolutionary pressure, is culturally universal, and appears spontaneously in all normally developing children.

However, despite intuitive connections between perception and creativity, meaningful empirical linkages between the two have not always been strong. For instance, [Flowers and Garbin \(1989\)](#) reviewed extant research on the intuitive connection between perception and creativity and noted lacunae in both research and theory specifically focused on these issues. In a rare exception, [Shepard \(1981\)](#) argued for a close relation between perception and creativity, claiming that implicit knowledge of visual relationships among objects, and rules for transforming those relationships, may constitute basic creative operations of the mind. Shepard further argued that decoupling normally involuntary processes from their perceptual source may allow those mechanisms to contribute to creative thought. More recently, [Palmiero and Srinivasan \(2015\)](#) thoroughly reviewed research on creativity and spatial abilities but found relatively little evidence supporting strong links between these constructs, at least based on how they are typically assessed in psychological research.

Psychometric Approaches

The most enduring empirical tradition exploring visual creativity has been taken up by creativity researchers with a psychometric bent. The challenge here is to devise tasks that can be administered to the general population and that are not limited or tied to domain-specific knowledge in a discipline like visual art. Such assessments thus represent a domain-general way of assessing creative potential and creative ideation. These typically take the form of visual or figural tests of creativity, in which participants generate creative responses to some visual prompt. For many years, visual aspects of creativity have figured prominently in the creativity testing literature. For example, in a collection of 225 creativity tests by [Torrance and Goff \(1989\)](#), figural image-making tasks made up about 9% of the total items.

Figural tests of creativity are valued because they are a simple alternative to verbal tests of creativity and are ecologically valid and easy to administer, even to children. [Pelowski et al. \(2017\)](#) provided a thorough review of visual creativity tests, which come in several major forms. Probably the most common version involves 'figure completion,' in which participants draw from visual cues pre-printed on paper. Early examples included the Franck Figure Completion Test, consisting of 36 rectangular fields, each with a simple geometric or curved figure that is used as the basis of a more complex drawing generated by the participant. More recently, the Torrance Test of Creative Thinking (TTCT) has become probably the most widely used instrument; it has been used in some 75% of creativity studies testing elementary schoolchildren and 40% of studies testing college students or adults. The figural aspects of the TTCT include ten figure completion items that are similar to those of the Franck Figure Completion Test, a picture construction task in which participants complete a drawing and assign a title, and a lines/circles task in which participants draw as many uses for a simple image as possible. Performance is scored on measures like fluency (the ability to create many images), originality, elaboration, abstractness of titles, and resistance to premature closure (a tendency not to quickly close off cues). Performance can also be assessed on criteria like storytelling, movement and action, unusual visualization, and richness of imagery. The TTCT has also shown fairly good validity in predicting real-world creativity.

Several alternatives to the TTCT have also been developed. These tend to share some aspects of stimuli and scoring with the TTCT and include the Creativity Assessment packet, Wallach-Kogan Creativity Test, and the Test for Creative Thinking-Drawing Production – the latter with emphases derived from Gestalt psychology. Other researchers have used more open-ended drawing tasks from imagination as a way of assessing visual creativity. One is Clark's Drawing Abilities Test, in which participants make drawings of a horse, a running person, a playground, and the participant's 'fantasy.' This test appears to be a reliable standardized instrument to identify artistically talented students, with CDAT scores correlating with teacher rankings of student success in classes for artistically talented students. (For details on all these tests, see [Pelowski et al., 2017](#).)

Insight

Besides creativity tests that directly require participants to generate a novel depiction as a domain-general index of creativity, researchers have also pursued other, less direct approaches. One is rooted in the phenomenon of insight: those emotional 'a-ha!' moments when a person has some novel realization, which have long been associated with creativity. Notably, even the word 'insight' suggests a sensory link (in-sight), along with the potentially rapid changes of interpretation inherent in many visual perception processes. For instance, identifying the content of out-of-focus photographs is the best predictor of individual differences in insight performance; notably, [Kozbelt \(2001\)](#) found that visual artists outperformed non-artists on this perceptual task.

In the laboratory, researchers have used ‘insight problems,’ which typically require some sort of reframing to achieve a solution, as proxies for real-world a-ha! moments. Many of these problems are verbal in nature, but others are more visual or spatial. Famous examples include the nine-dots and matchsticks problems. In the nine-dots problem, nine dots in a square 3×3 array must be connected by four straight continuous lines. In the matchsticks problem, six matchsticks must be put together to form four equilateral triangles. Typically, solutions to such problems require participants to perceptually reorganize the stimulus to overcome some default bias or implied constraint in the problem. In the case of the nine dots problem, the constraint is the *Gestalt* formed by the nine dots, and the solution requires drawing the lines beyond the boundaries implied by the ‘square.’ In the matchstick problem, it is the two-dimensional presentation of the problem, and the solution requires making a three-dimensional pyramid with the matchsticks.

Achieving the perceptual reorganization necessary to solve such problems may require deliberate executive control or attentional flexibility; alternatively, the solution may arise more spontaneously from resting brain state activity. Such findings serve as a reminder that many aspects of neural processing, beyond the sequential stages of perception, impact creative thought. In passing, note that this point also extends to other forms of representations – linguistic, mathematical, kinesthetic, and so on – which also interact with perceptual processes and contribute to creative thought.

Imagery

The nature of the human capacity for generating internal visual representations has long been debated within the ranks of cognitive science – mainly in terms of whether such representations are ‘really’ visual, rather than being epiphenomenally so. Neuroimaging research has revealed that visual perception and visual imagery draw on most of the same neural underpinnings (Kosslyn et al., 2006), though the issue of what it would mean to characterize the ‘true’ nature of a mental representation remains a thorny philosophical issue.

The topic of visual imagery is of great interest for the study of creativity, as it has traditionally been anecdotally implicated as a driver of creative thought – particularly in the process of generating new ideas. Many empirical studies have sought to understand the role of imagery in creativity. Among the most prominent lines of inquiry is the so-called ‘creative cognition approach’ pioneered by Finke et al. (1992). This research proposed to understand creativity mainly in terms of the application of well-understood cognitive psychological principles and mechanisms, rather than resorting to more exotic modes of cognition as explanations. Of the many notable contributions of this approach, the notion of ‘pre-inventive structures’ is probably the most relevant for understanding the role of mental imagery in creativity. Pre-inventive structures are internal precursors to the creative act. They frequently have a visual component, often taking the form of symbolic visual patterns and diagrams or representations of three-dimensional objects. The role of such structures in the creative process have been investigated in numerous lab experiments. In one representative study, participants were shown a set of simple objects and were asked to combine them into a new invention, whose basic category (like furniture or vehicles) was specified either before or after they had put the parts together. Inventions judged as creative were more likely to occur when the basic category was specified after the parts were assembled.

Also relevant is other work within the creative cognition approach, an alien creature invention task developed by Tom Ward. In the basic version of this task, participants are asked to imagine traveling to another planet and encountering some alien life form. The task is simply to draw a picture and write a short paragraph describing the alien. Despite the almost completely unconstrained nature of the task, Ward and others have repeatedly found that participants evince little creativity, rooting their creatures’ characteristics mostly in line with those of familiar real-life or science-fiction examples. From the standpoint of visual perception and creativity, this ‘structured imagination’ taps into both perceptual aspects (recalling the appearance of specific exemplars from memory) as well as the interface between perceptual and conceptual knowledge (as in participants’ deployment of categorical knowledge in approaching the task).

In addition to research within the creative cognitive approach, other scholars contributed valuable concepts about the nature of creative imagery. For instance, consider two notions described by Rothenberg (1979): Janusian thinking and homospatial thinking. Janusian thinking is the ability to imagine and hold in mind two opposite or contradictory ideas, concepts, or images simultaneously. Homospatial thinking consists of actively conceiving two or more discrete entities occupying the same space, which can lead to the articulation of new identities. Such processes are often highly visual in nature, and Rothenberg identified numerous instances of visual artists engaging in such thinking. Laboratory research also revealed that artists presented with two superimposed images made more creative drawings than artists presented with similar but non-superimposed combined-composite control stimuli. While this latter result does not directly tap into internal visual imagery *per se*, it does suggest something of the fluid indeterminacy of imagery and its productive role in creative ideation (See Janusian, Homospatial and Sep-Con Articulation Processes).

However, despite an oft-touted anecdotal relationship between imagery and creativity, the overall empirical relation between the two appears to be rather slight. For instance, one meta-analysis of 18 papers on visual imagery and divergent thinking ability (Leboutillier and Marks, 2003) found that self-reported mental imagery was reliably associated with performance on divergent thinking scores but explained only about 3% of the variance in the data sets. Separate analyses of important characteristics of mental imagery and two types of divergent thinking showed similar effects across variations in question and test formats, suggesting only minimal support for the claim that mental imagery is an important correlate of creativity – at least when creativity is construed in divergent thinking terms.

Personality

Besides approaches in which creativity is characterized mainly via underlying mental processes, personality is another factor that has long been associated with creativity. Of the 'Big Five' well-established dimensions of personality, that of openness to experience is the most consistently and strongly associated with creativity, or at least creative potential (Feist et al., 2017). It is easy to see that someone who was neither curious about nor open to new experiences would be less likely to show meaningful creativity.

What does personality have to do with visual perception and creativity? Some research suggests incipient connections between the two constructs. For instance, openness to experience correlates with the ability to select 'aesthetically superior' pictures and with more positive ratings of abstract and representational art (see Pelowski et al., 2017). Recent research (Antinori et al., 2017) suggests that openness to experience is positively associated with an additional low-level aspect of visual perception – specifically, binocular rivalry, where the brain alternates between mixed and unmixed percepts. Participants higher in openness to experience showed longer mixed percept times, an effect that increased following a positive mood induction. While binocular rivalry is not a direct productive measure of creativity, it has parallels with homospatial thinking and is consistent with the idea that creative people perceive the world differently than less creative people.

Domain-Specific Aspects of Visual Creativity

The preceding suite of approaches represents a domain-general view of creativity. Modern discussions of creativity have long been characterized by debates on issues like the extent to which creativity is better considered as a domain-general or domain-specific phenomenon and how to consider different levels of creative achievement, ranging from minor personal insights to history-making achievements. When manifestations of creativity can be regarded as fundamentally greater, more impressive, or more impactful, they tend to be more domain-specific. So perhaps the quick-to-administer and domain-general laboratory tests of creativity described above are impoverished, trivializing the real phenomenon of interest.

A more meaningful characterization of creativity might require more elaborate testing conditions, more expert participants, and more domain-specific conceptions of creativity itself. How have researchers addressed the potential link between visual perception and creativity in more domain-specific ways?

Creativity in Visual Art

Art is a paradigmatic domain for the study of visual perception and creativity. There is a long tradition of using domain-specific artistic production tasks and artist participants to better understand the nature of creativity. Since the creative behavior of artists is often strongly rooted in visual response, artists' activities can inform aspects of their visual processing, even if these are not tested directly in a psychometric way.

One of the most seminal and widely cited study of creativity is that of Getzels and Csikszentmihalyi (1976), who studied college-level art students. Participants were given a display of objects and were asked to use them to set up an arrangement and to draw it, in any style that they liked. Getzels and Csikszentmihalyi introduced the concept of 'problem finding' to account for the more creative artists' discovery-oriented behaviors, like handling more objects (and those more intensively) prior to starting drawing or taking longer for the final structure of the drawing to become evident. Subsequent researchers have borne out many of Getzel and Csikszentmihalyi's findings. For instance, Kozbelt (2008) observed college-level art students at work on a similar still-life drawing task, but with more fine-grained video coding of the hour-long sessions. While the initial selection and handling of objects was associated with the ultimate judged creativity of the drawings, even more important was the amount of revision, erasing, and reworking while drawing: more revisions were associated with greater creativity. Other studies used creative tasks involving collage or logo design, as well as structured interviews, to assess other aspects of the structure of artistic creativity, with similar results (for a review, see Kozbelt, 2008) (See Problem Finding).

A complementary line of research looked at the in-progress states of emerging works of art, either in the laboratory or by using the photographic evidence of acclaimed works by eminent artists. In line with other research on artistic creativity, a central finding from such studies is that artworks often undergo substantial visual changes as they progress. Such changes go beyond the mere filling in of predetermined elements and include significant alterations to the structure of the overall composition and the redeployment of many visual features throughout the process of creation. Sessions leading to more creative final outcomes tended to be characterized by a greater fluctuation in quality as they progressed, compared to 'safer' drawing sessions, which did not take as many risks, change in quality in a more linear way as they progressed, and ended up being judged as less creative final products.

What is perhaps most interesting here is the pervasiveness and intensity of many artists' revisions, given that in an ill-defined domain like art, there is no logical requirement for making such changes. Instead, these revisions emerged from artists' own creative standards and sensibilities and reflected their striving to achieve complex aesthetic goals. These goals were expressed through artistic media whose control depends on extensive domain-specific experience and knowledge. Importantly, revisions were mediated by what appear to be very flexible underlying perceptual processes, with both creative and evaluative components. Such results are consistent with general findings on experts' big-picture sensibilities on domain-relevant tasks and with creators' general willingness to take risks and make revisions to works-in-progress.

Perception in Visual Art

Besides studies that explore artists' creative processes, another line of research has focused on artists' perceptual abilities. Visual perception involves a general sensory modality; domain-specific creativity in art exploits some subset of visual processes that are relevant to that domain. Artists need to be able to perceive the visible world in special ways, which lend themselves to creating depictions that reflect those perceptions as expressed through specific artistic media. If artists routinely look at the world with the goal of rendering it, certain kinds of perceptual abilities may become enhanced. Overall, domain-specific expertise has substantial effects on experts' perceptual processes, particularly for familiar stimuli within their domain. Learning in complex domains involves learning to *see well*: that is, tuning perception to highlight task-relevant features and deep (rather than surface) properties, attending to important aspects of problems to control the time course of reasoning, and recruiting and restructuring neural regions to accomplish skilled perceptual tasks (Landy, 2018).

In recent years, numerous studies have documented and explored the nature of artists' perceptual advantages over non-artists – that is, how artists learn to see the world differently. For instance, Kozbelt (2001) found that not only did artists draw more accurately than non-artists, but they also outperformed non-artists on several visual perception tasks requiring visual analysis – like recognizing the subjects of blurry photographs – but which had nothing *per se* to do with drawing. Drawing performance and perception performance were positively correlated, and partial correlational analyses suggested that artists' perceptual advantages are developed mainly to the extent that they are useful in drawing. Subsequent research has largely corroborated these findings, while refining which aspects of perception typically yield differences, and deepening the underlying theoretical treatment (for a review, see Kozbelt and Ostrofsky, 2018). Among the robust results on artists' visual advantages are a more flexible top-down deployment of attention, enhanced recognition of degraded visual stimuli, better visual memory, and a greater understanding of the structure of objects. Evidence for purported advantages in lower-level aspects of visual perception and cognition – like overcoming perceptual constancies or the effects of visual illusions – is more mixed (Perdreau and Cavanagh, 2011).

Such research suggests that advantages in many aspects of visual perception and cognition are characteristic of a prototypically 'creative' group of people, visual artists. While these results are suggestive of an association, more research is needed to corroborate this point in a meaningfully domain-specific way.

Visual Perception in Other Domains

What about other domains? Beyond visual art, the relation between perception and creativity has also been explored. One long-standing assertion is that imaginative visualization processes can be useful for engendering major creative insights: August Kekulé's conception of the ring structure of the benzene molecule via a dreamy vision of a snake biting its own tale is prototypical here. While such anecdotes are suggestive, stronger evidence, involving somewhat more systematic investigation of these issues, has also been undertaken.

For instance, the psychological research literature on expertise suggests that in many domains, experts learn to pay attention to important aspects of problems. The extent to which gaining expertise in a domain literally changes the way a person perceives domain-relevant stimuli is a nuanced question. However, since many aspects of perception can be modulated through experience, it makes sense that deep knowledge of a domain could influence perception and thus impact potential creativity – though the details of this dynamic remain murky (See Expertise).

Beyond basic perceptual functioning, other facets of visualization are also important in domains outside of art. One aspect that has been studied extensively is the role of diagrams and other simplified external representations, which focus attention on the important attributes of a situation (Tversky, 2011). The ability to understand and to generate such representations calls upon varied visual and spatial skills. The empirical consistencies found among such representations shed light on how people think and have practical implications for pedagogy and for creative design processes.

In terms of more broadly conceived individual differences related to perception, spatial reasoning – that is, the ability to generate, retain, retrieve, and transform well-structured visual images – has been the subject of considerable recent research. Spatial ability is often considered a key attribute of intelligence as well as creativity – perhaps especially in mathematical, scientific, and engineering domains (Palmiero and Srinivasan, 2015). In an important and very large-scale ($N = 400,000$) longitudinal study, Wai et al. (2009) found that a high level of spatial ability assessed during adolescence remained a salient psychological attribute among those who subsequently achieve advanced educational credentials and occupations in STEM domains. Such results provide strong support for the notion that spatial ability plays a critical role in developing expertise in STEM domains. They also underscore the diversity of ways and domains in which perceptual factors may play out in terms of creativity.

Conclusion

While the topics of creativity and visual perception have each been pursued independently by researchers, links between them remain somewhat elusive – especially links based on direct, robust, and rigorous research. However, several converging lines of evidence broadly support the importance of perceptual and visualization processes for creative productivity. These lines of evidence encompass both domain-general and domain-specific approaches, the latter including artistic and STEM domains. While some thorough literature reviews and meta-analyses suggest that links between visual-spatial ability and creativity may be weaker than

previously thought, it is important to note that considerable research still needs to be done. Greater consistency and replication efforts among future studies – which have historically targeted different tasks, abilities, domains, and kinds of participants – should yield a more precise and nuanced assessment of the real links between aspects of perception and aspects of creativity. Especially informative would be studies grounding specific perceptual abilities in the dynamic activity process of high-level creators working on complex, ecologically valid creative activities.

Introduction

Democracy, a term coined by Greeks thousands of years ago, was and still is what people in different parts of the world seek. Democracy is defined as 'a system that provides citizens with political rights which they are free to exercise in a political structure open to public participation and electoral competition' (Trantidis, 2017, p. 67). When properly practiced, democracy ensures that all citizens have equal rights to participate in the decision making process that affects their personal well-being and nation. The salient feature of democracy is *voting*. The Oxford English Dictionary defines voting as 'A formal indication of a choice between two or more candidates or courses of action, expressed typically through a ballot or a show of hands.' Voting can be considered a double-edged sword: it can bring to power a Hitler or a Mandela. Both came to power by appealing to voters to accept their ideals and vision. Although the term voting is not restricted to politics (e.g., people might vote for a place to have a dinner or vote for the best idea to solve a particular problem), its significance in politics surpasses any other aspect of its use in the social world.

The focus of this article is on voting as a political tool and how creativity is affected by such a tool. What does voting have to do with creativity? To answer this question it is important first to shed light on the characteristics of a creative individual. This will help understand the relationship between creativity and political party; that is, the effect creativity has on an individual's preference to select a particular political party. The essay presents recent investigations that discern the relationships among conservatism, liberalism, and creativity, as well as new evidence showing how the party in power affects research funding. The summary section suggests a new term to distinguish between the good and the bad use of voting as a significant democratic tool, that is, 'the creative vote.'

Characteristics of Creative People

The scientific study of creativity began in the mid 20th century. Now, after 70 years psychologists and educators have a better understanding of this exceptional human ability. It is important to emphasize the 'scientific' aspect of creativity research, for two reasons. One, the term 'scientific' indicates that researchers use rigorous methods to test different hypotheses and to answer research questions. Two, people need to know that research findings in this field are reliable and based on scientific facts (Runco, 2019).

Since creativity is not a unidimensional ability, the study of creativity encompasses different perspectives and different approaches to understand creativity such as creative process, creative product, creative environment, and creative personality. This paper claims that the creative personality is an important element when discussing the relationship between creativity and the selection of a political party. What do scientific studies on creative personality tell us about the characteristics distinguishing creative individuals? Luckily, research on this topic abounds and there is a consensus that creative individuals are imaginative, curious, independent, original, willing to take risks, unconventional, flexible, open to experience, and tolerant (Feist, 1998; Feist and Barron, 2003). Among these characteristics, openness to experience, and tolerance are of high importance when discussing the relationships among creativity, conservatism, and liberalism. In all democratic countries there are at least two political parties, which is a healthy, given that diversity is good for creativity. Diversity allows people to discuss issues from more than one perspective. In a recent study on the relationship between creativity and conservatism, Runco et al. (2017) reported that creativity was positively related with racial diversity. Also, the second characteristic tolerance was among the highly correlated personal variables. Tolerance is one of the 3 Ts in Richard Florida's theory of creative class. Florida defined tolerance as 'openness, inclusiveness, and diversity to all ethnicities, races, and walks of life' (Florida, 2003, p. 10). Tolerance is linked to creativity because it allows diversity, and diversity is good for creativity. Tolerance is also important for originality since original ideas are nontraditional and uncommon, which requires risk tolerance (Runco, 2019).

Political parties, regardless of country, can be placed on a continuum ranging from left-wing (highly liberal) to right-wing (highly conservative). Examples of liberal parties are the Democratic Party in the United States and the Labour party in the United

Kingdom; conversely, the Republican Party and the Conservative Party are examples of conservative parties in United States and United Kingdom, respectively. One of the definitions for the term conservatism is ‘The quality of not usually liking or trusting change, especially sudden change’ (Cambridge Dictionary). Conservative people tend to be less flexible, less tolerant, and not in favor of change. This is exactly opposite to creative traits mentioned previously. A number of investigations have showed that conservatism and creativity are negatively related with each other. To put it differently, ‘the more conservative a person is, the less likely it is that he or she will do creative things’ (Runco et al., 2017, p. 331). That is not to say that people following conservative parties have fewer creative abilities compared with those in liberal parties. That is why personality should be considered, because we behave based on our beliefs and values. People who do not value creativity will not activate their creative potential. This argument is supported by number of investigations cited in the next section.

Conservatism, Liberalism, and Creativity

Several empirical methods have been employed across studies that examined the relationship between creativity and conservatism. In some recent investigations, voting patterns were used to estimate liberalism and conservatism (e.g., McCann, 2011a; 2009; Runco et al., 2017). Each US state was determined to be open (liberal) or conservative based on the winning party in that state – Democrat or Republican. Creativity was based on the number of patents granted per state, with conservatism being based on the percentage of Republican votes per state.

McCann (2011a,b), for example looked at the relationship between creative productivity, operationalized as the number of patents granted per state, and conservatism, operationalized as the percentage of Republican voters (for George W. Bush) in 2004, with openness being measured by The Big Five personality questionnaire. Patents per state was positively correlated with openness ($r = 0.50$) and negatively correlated with conservatism ($r = -0.65$). McCann concluded, ‘it is quite clear that patents are more likely to be issued to residents of states in which there generally is a lower level of conservatism’ (p. 342). In another study, McCann (2011a,b) used Richard Florida’s Creativity Index scores (3 Ts: Talent, Technology, and Tolerance) to assess the relationship between openness and conservatism. The Creativity Index scores of participants in each state captured openness, with conservatism measured by the percentage of George W. Bush voters in the 2000 presidential election. The same conclusions were reached: conservatism was negatively correlated with creativity, while a positive relation exists between creativity and openness. McCann’s findings were confirmed by Runco et al. (2017), but in these study counties were the unit of analysis instead of states. Runco et al. (2017) obtained voting data from 2581 counties in the United States and patents granted in each of these counties between 2011 and 2015. Conservatism was measured as the percentage of voters who voted Republican in the 2016 Presidential election. Again, creative accomplishment was negatively correlated with conservatism.

Jost et al. (2003) conducted a meta-analysis study looking at variables predicting political conservatism. Their results indicated that conservatism was negatively correlated with openness to experience ($r = -0.32$), uncertainty tolerance ($r = -0.27$), and positively correlated with intolerance of ambiguity ($r = 0.34$). Their meta-analysis covered 12 countries: United States, England, New Zealand, Australia, Poland, Sweden, Germany, Scotland, Israel, Italy, Canada, and South Africa.

Dollinger (2007) also studied the relationship between creativity and conservatism. He used the Creative Behavior Inventory (CBI) to assess creative accomplishment, The Big Five Inventory to assess openness, and Consensual Assessment Technique (CAT) to assess a figural divergent thinking test. In this study, conservatism was assessed by using Henningham’s C-scale, which is a 12-item scale of social conservatism. Openness, creative achievement, and creative products negatively correlated with conservatism: ($r = -0.27$), ($r = -0.22$), and ($r = -0.27$) respectively. The following section offers further evidence supporting the claim that creative productivity negatively correlates with conservatism. In this overview of national research grants, the number of awards used becomes a measure for creative productivity, while the party in power becomes a measure for conservatism.

New Evidence from NSF Research Grants

The question this section aims to answer is whether Republican leadership (conservatism) negatively affects the number of research grants. To answer this question, grants offered by the National Science Foundation (NSF) were counted for the period 1981 to 2016. Data dated earlier than Ronald Reagan’s presidency (1981) were incomplete. This search covered twenty-six years in which five US presidents took office. The least number of awards occurred in 1982 (6070) and the highest number occurred in 2009 (15,581). Since 1981, the NSF has funded 370,372 projects [awards] with 188,503 awards distributed over the 20 years in which Republicans were in power; conversely, there were 181,869 awards distributed over the 16 years that the Democrats were in power. As Fig. 1 shows, the average number of awards per year for Republicans was 9425.1 (45.33%), while the average number of awards per year for Democrats was 11,366.8 (54.67%). On average Republican conservatism accounts for a 1941.7 decrease in NSF projects funded per year.

A closer look at the number of awards since 2001 shows that the number of awards granted during George W. Bush’s presidency ranged between 10,427 and 12,054 whereas the number of awards granted during Barack Obama’s presidency ranged between 11,568 and 15,581 (see Fig. 2). This adds to the evidence that conservatism is negatively associated with productivity operationalized as the number research awards funded by the NSF.

NSF Awards 1981-2016

Figure 2 The Number of Awards Granted by NSF (2001-2016)

Conclusion

The previous sections explored the relationships among creativity, liberalism, and conservatism. There are many reasons that voters may expect less creativity from conservative people and parties. Conservatives conform to what is conventional, they focus on traditions, prefer stability, and resist change. This is just the opposite of creative thinking, which is characterized by originality, unconventionality, flexibility, tolerance, and openness. In fact, liberal versus conservative behavior is driven by two different motives; the desire to create versus the fear of change.

This chapter presented several studies that investigated the relationship between creativity and conservatism. Although different empirical methods were used to examine the relationship, the conclusions were the same: liberal thinking has a positive impact on creativity, while conservative thinking has a negative impact on creativity.

Practicing democracy in this chapter, it is the people's decision whether they vote for a person or a party that values creativity, and thus, encourages originality; or vote for a person, or to a party that maintains the status quo, and thus, encourages conventionality.

In other words, people need to decide between a creative versus uncreative vote. The former resulted in bringing to power people who support and encourage creativity, while the latter results in bringing to power those who are intolerant and distribute the culture of fear.

Introduction

Is personal and societal creativity positively associated with peace and prosperity? How does warfare affect the creative output of a given individual or nation? Does war determine both quantity and quality of cultural and intellectual activity?

A superficial glance at history might lead us to suspect that war features positive relation with creativity. At the individual level we might cite the example of Ludwig van Beethoven: Many of his masterworks seem to have appeared during the height of the Napoleonic Wars. Indeed, he had originally planned to dedicate his Third “Eroica” Symphony to Napoleon himself. [see Beethoven] At the societal level we might mention the Golden Age of Greece, a period of high cultural achievement framed by the Persian and Peloponnesian Wars. The Italian Renaissance provides another apparent example. Did not Leonardo da Vinci devote part of his creativity to designing weapons? And did not Michelangelo help design fortifications? Of course, it is also possible to come up with counterexamples. On the one hand, the famed Pax Romana – a period of relative peace during the Roman Empire – also was associated with a great cultural florescence, such as the so-called “Silver Age” of Latin literature. On the other hand, it would seem that World War II had a devastating impact on creativity in Europe and Asia.

Rather than continue to pit one anecdote against another, it is possible to address this question in a more objective and quantitative manner. In particular, the optimal approach is to apply historiometric methods to biographical and historical data [see Historiometry]. Fortunately, a large number of diverse studies have been conducted on this issue. The vast majority of these investigations focus on how war might influence creativity, so that research will be discussed first. But a smaller number have looked at how creativity might be involved in war, a possibility examined toward the end.

Effects of War on Creativity

In general, war can affect creativity in two ways: quantitative and qualitative. The first concerns the actual output, such as the number of creative products produced in a given year. Does warfare help or hinder the odds that creativity will appear? The second concerns the nature of the output, such as its thematic content or stylistic characteristics. Does peacetime creativity look different than wartime creativity?

[☆] *Change History:* Jan 2019. Dean Simonton updated the text throughout the article.

This article is an update of D.K. Simonton, War, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 509–514.

Quantitative Effects

How does war affect creativity? It turns out that this question is much more complex than first meets the eye. Research cannot begin to provide an answer until the investigator first responds to three subsidiary questions.

First, what exactly is meant by war? At the very least two different kinds of war can be distinguished. On the one hand are the wars between sovereign states, such as World War I among several European nations. This type of conflict is sometimes referred to as an international war. On the other hand are the wars that take place within a given sovereign state, such as the English Civil War of the mid-17th century. This type of conflict is sometimes called an intranational war. However, these two labels do not exhaust all of the possibilities. For instance, another kind of war is the imperialistic or colonial war where one modern nation-state subjugates foreign peoples, especially those who have a tribal rather than national political structure. Needless to say, different varieties of war need not have the same impact on creativity. Complicating the situation all the more is the issue of how to assess the state of war. Is it merely a matter of counting the number of nations that have declared war? Or should the number of pitched battles or war casualties be taken into consideration? What about the war's economic costs?

Second, what exactly is meant by creativity? It has become customary to distinguish between two levels of creativity, "little-c" or everyday creativity and "Big-C" or genius-level creativity [see *Everyday Creativity*]. War might not exert the same influence on both. In addition, it is obvious that creativity appears in many different disciplines. At the very minimum, scientific creativity must be separated from artistic creativity. Yet it may be necessary to make finer distinctions as well. Certainly more expensive art forms like architecture might suffer more from military conflict than less expensive forms like poetry. In the case of the sciences, applied disciplines like medicine and technology may receive a boost at the expense of pure disciplines like botany and mathematics.

Third and last, what is the unit of analysis? This turns out to be a very complex issue. To begin with, the investigator must decide whether the units are going to be individual or aggregate. Individual units concentrate on samples of creators or their creative products. Such units are designed for asking whether people are less creative if they grow up in wartime conditions. In contrast, aggregate units concern samples of individuals organized into larger entities, such as nations or civilizations. Such units are best for addressing whether societies that more often engage in war are more likely to have fewer creative geniuses. Another issue is whether the units are to be cross-sectional or longitudinal. Cross-sectional units could entail samples of individual creators or independent nation states. Longitudinal units, in contrast, would examine one or more units across time, where those units may be either individual or aggregate. For example, a researcher might examine how war affects the annual output of creators or nations. Most often the units are arranged into time series and thus subjected to some kind of time-series analysis. Whenever time series are used, the investigator must decide on the size of the longitudinal unit. The most common choices are years, decades, or generations, where the latter is taken as somewhere between 20 and 25 years in length. Shorter time-series units are optimal for studying the momentary effects of war whereas longer units are optimal for studying the more enduring consequences of war.

The answer to these three questions largely determines the empirical results. Indeed, the one secure conclusion that can be drawn from the literature is that the relation between war and creativity depends on the definitions of war, creativity, and the units of analysis. To appreciate this dependence, below I report the key findings under two headings, aggregate units and individual units.

Aggregate Units

Some researchers have counted the number of creative geniuses appearing in consecutive generations in the history of an entire civilization, where the creativity could come from any major domain in the arts and sciences. The fluctuations in these counts were then compared with the occurrence of international wars (sometimes weighted by the number of casualties). The same findings have appeared for both Western and Eastern civilizations: Military conflicts among independent states have no relation, positive or negative, with societal creativity. This null result explains why it is so easy to find examples of creativity under wartime conditions and creativity under peacetime conditions. Both possibilities occur with roughly equal likelihood.

Even so, by various changes in the methodological design, it becomes possible to observe some variety of war-creativity connection. For example, [Simonton \(1980\)](#) scrutinized the relation in Western civilization since the Renaissance, but introduced the following changes: (a) the unit of analysis was the year rather than the generation, (b) creativity was restricted to science and technology, (c) the creativity measure entailed an annual count of discoveries and inventions rather than individual scientists and inventors, and (d) war was split into four different categories, namely balance-of-power (or international) wars, civil (or intranational) wars, imperial (or colonial) wars, and defensive wars (when Western civilization was under attack by a non-Western civilization, such as the Ottoman Empire). In this case, negative effects were observed for balance-of-power and defensive wars. Over all, the following balance-of-power wars had the most destructive effect on discovery and invention in modern Western civilization: the Thirty Years' War, the Napoleonic Wars, and the two World Wars. Other inquiries have replicated this finding, particularly in the case of World Wars I and II. The latter even had an adverse effect on creative contributions in psychology.

The preceding studies concentrated on the concurrent or contemporaneous relation between societal creativity and war. The amount of war in a given year was directly compared with the number of discoveries and inventions in the same year. Yet it is also possible that the causal relation between the two variables is time lagged. That is, the impact is not immediate but rather manifests itself after a decade or more. This possibility has been tested using generational time-series analysis. In this technique historic creators and political events are tabulated into consecutive 20-periods called generations. The number of creators in generation g can then be correlated with the event counts in generation $g - 1$, or 20 years earlier. Because creators are assigned to the time-series units according to their peak productive

period (most often taken as age 40), creators in generation g would be in their developmental phase in generation $g - 1$. Hence, this time-lagged function can assess whether certain political events, including war, exerts an effect on creative development.

Although the allowance for time-lagged generational does not alter the picture for international war, the provision does change conclusions for various kinds of intranational war. Most prominently, revolts and rebellions directed against the hegemony of imperial states tend to increase the level of creative activity in a civilization. It seems that large empires tend to enforce a degree of cultural homogeneity that is antithetical to creative development. Interestingly, another kind of internal violence, namely, political instability, can have the opposite effect after a generation delay: 20 years after military revolts, coups d'état, and political assassinations a civilization tends to witness a decline in the number of creative geniuses.

One peculiarity deserves special mention: The impact of the diverse varieties of warfare depends on the domain of creativity under scrutiny. Most notably, creativity in the arts tends to be less affected than creativity in the sciences. Scientific creativity may require more ideal conditions than artistic creativity.

Individual Units

The empirical findings reported in the previous section all depended on data aggregated across large numbers of creative individuals. Indeed, many of the investigations tabulated thousands of geniuses into 20-year generational time series. It is conceivable that such aggregation obscures the relation between war and creativity. Especially in a large civilization area, some creators will be more directly affected by war than others. While World War I was quite injurious to creativity in Europe, its consequences for creativity in the Americas was minimal. Thus, it might be better to investigate how war affects creativity at the individual rather than aggregate level.

Unfortunately, far fewer researchers have taken this alternative approach. [Simonton \(1977\)](#) examined creative output in 10 top classical composers and still found that international war had no influence one way or another. Another study, using a very similar design, [Simonton \(1985\)](#) showed that the creative output of 10 top psychologists declined during times of international war. Both of these investigations counted output in 5-year periods across each creator's career. Potentially even this degree of aggregation may mask the more transient effects of war. For instance, [Borowiecki \(2014\)](#) counted the output of 115 classical composers in annual units, and thereby identified war effects (albeit the specific effect depended on the type of war). Yet another alternative is to use an even finer unit of analysis, namely individual creative products. For instance, [Simonton's \(1986a\)](#) study of 1935 compositions in the classical repertoire found that the most frequently performed works are less likely to be created during times of international war. So this particular form of artistic creativity may be encouraged by peacetime conditions.

Qualitative Effects

Even though certain types of war appear to have quantitative effects on specific kinds of creative activity, these effects are weak. Seldom is a military conflict so extensive that it shuts down creativity altogether. Because some creators will reside sufficiently far from the war zone, creative products will still appear, even if at a reduced rate. Consequently, it becomes possible to ask whether the works that appear in times of war differ from those that emerge in times of peace.

Various historiometric studies have addressed this question using an even more diverse set of methodological approaches. Probably the most important difference is the domain of creativity that is under investigation. Clearly, the thematic and stylistic parameters of creative products are contingent on the domain of creativity. For instance, a musical composition cannot be assessed by the same criteria as a scientific journal article. Accordingly, it is optimal to organize this section according to creative domain. More specifically, the discussion here will separately cover music, literature, and philosophy, and science. The visual arts appear to be missing from this survey, but there appear to be no published studies of how war might affect the style or content of paintings, sculpture, and architecture. Perhaps this omission reflects the difficulty of analyzing the visual arts for this purpose.

Music

One approach to assessing the qualitative effects of war is to apply content analysis to creative products that are generated under either wartime or peacetime conditions. The content analysis may take two major forms: subjective and objective. Subjective content analysis requires trained human judges to apply well-defined coding schemes to a given document or artifact. In contrast, objective content analysis requires that a computer program apply the coding schemes without the intervention of a human being. Both of these approaches have been applied to compositions that make up the classical repertoire. The empirical research using these methods has shown that music is often responsive to the stresses and strains occurring in a composer's personal life. And it is hard to imagine war having any less of an effect. In point of fact, investigations have indicated that concurrent warfare has a major impact on the stylistic content of compositions. For example, according to [Simonton \(1986a\)](#), compositions penned during wartime exhibit much greater variation in melodic originality; extremely predictable and extremely unpredictable themes being found in the same work. It is almost as if highly stressful contemporary events polarize the creator's emotional reactions, inspiring vast mood swings between resignation and despair, hope and fear. Furthermore, [Cerulo \(1984\)](#) found that the stylistic impact of war appears to intensify to the extent that the composer resides close to the actual war zone. Shostakovich's Leningrad Symphony, written during World War II, may provide a graphic auditory example of the magnitude of this polarization of trite and profound in melodic material.

Given that classical music constitutes a relatively abstract form of artistic creativity – where style seems more crucial than content – it might seem surprising that compositions are so responsive to external conditions like war. In the next domain of artistic creativity such a connection would be more likely expected.

Literature

Ben Jonson said that William Shakespeare “was not of an age, but for all time.” Nevertheless, it is evident from the empirical literature that he definitely wrote his plays for his own age and time. The thematic material often reflected current events, particularly the most dramatic of these events (Simonton, 1986b). And it is difficult to imagine an event more striking than military conflict. So, in line with expectation, Shakespeare’s thematic content tended to be responsive to wartime circumstances. In the first place, whenever a foreign power attacked his native land, England, his plays had a tendency to discuss political expansion, empire, and conquest as the goals of war. In addition, various revolts and rebellions would stimulate discussion of life’s conflicts. Even conspiracies against the monarch left an imprint on the Bard’s plays. Nor was Shakespeare unique in his responsiveness to international and intranational war. Comparable results appear to hold for the ancient Athenian playwrights Aeschylus, Sophocles, Euripides, and Aristophanes (Simonton, 1983).

Content analytical studies have found that international war affects the content of poetry as well. Poems written during wartime are noticeably different from those written in peacetime. For instance, one investigation scrutinized how concomitant war casualties related to the content of French and English poetry (Martindale, 1975). When wartime deaths and injured intensified, poets were more likely to treat moral imperatives (more often using such words as should, right, and virtue in their poems) but were less likely to invoke the theme of chaos (less often using such words as wild, crowd, and ruin). Just as intriguing, war intensity was positively associated with content indicative of rationality, restraint, and control. All in all, wartime poems place more emphasis on maintaining the moral order in the face of evil and chaos.

Finally, it is worth mentioning a curious relation between war and a very specialized literary theme – that of Don Juan. Although Don Juan legend originated in Spain, he proved to be such a popular character that various versions appear in other national literature as well. In any given literary tradition, the frequency of Don Juan versions correlates positively with how much that nation was engaged in warfare (Winter 1973). What makes this association most interesting is that the Don Juan theme can be linked with the need for power. The character’s sexual conquests are indicative of interpersonal dominance, just as war is an instrument of international dominance. Because war itself is also connected with power motivation, enhanced interest in the Don Juan reflects a national shift toward the need for power. Significantly, this literary theme peaks about a decade after the peak in warfare.

Philosophy

Philosophers are apparently no more immune from war’s influence than are the composers and writers. This impact was demonstrated in an extensive generational time-series analysis of over two thousand thinkers from the ancient Greeks to modern Western civilization (Simonton, 1976). A team of experts first rated the thinkers on the stances on several key intellectual issues. These issues included the fundamental nature of reality (ontology), the basis for human knowledge (epistemology), and the criteria for good and evil (ethics). These thinkers were then tabulated into separate generational time series for each philosophical position, yielding a measure of fluctuations in major intellectual ideas. Because war was hypothesized to function as a developmental influence, a time-lagged analysis was used. That is, the number of philosophers in generation g was related to the amount of war in generation $g - 1$, or 20 years earlier. Significant relations were found for both intranational and international war.

1. Intranational war, and especially substantial civil disturbances, has a polarizing impact on intellectual debate, again after a one generation delay. To be specific, 20 years after such collective violence philosophers tend to advocate (a) empiricism (all knowledge comes through the senses), rationalism (all knowledge comes through reason), and mysticism (all knowledge comes through revelation); (b) materialism (matter is the fundamental basis of reality) and idealism (spirit or mind is the fundamental basis); (c) eternalism (reality is unchanging) and temporalism (reality is in constant flux), (d) realism (abstract ideas really exist) and nominalism (abstract ideas are but names in our language); (e) singularism (the individual is of primary importance) and universalism (the society is primary); (f) determinism (everything is caused) and indeterminism (humans have free will); and (g) the ethics of happiness (good and evil based on pleasure), the ethics of principles (good and evil decided by universal rules), and the ethnics of love (good and evil guided by compassion). It is as if the political polarization that causes intranational war in generation $g - 1$ induces ideological polarization in generation g .
2. In contrast, international war has a far more selective effect, and a negative one, discouraging the emergence of certain beliefs. In particular, one generation after major international warfare philosophers are less likely to advocate empiricism, temporalism, nominalism, singularism, and the ethics of happiness. In other words, thinkers are less prone to argue that knowledge comes through the senses, that reality is constantly changing, that abstract ideas are but names, that individuals have priority over society, and that moral decisions should be based on what causes pleasure and pain. Evidently, these particular stances are not favored during wartime conditions, perhaps because these beliefs might be antithetical to the extreme patriotism and self-sacrifice required for the war effort. So, future philosophers who grow up under such circumstances are less likely to espouse these beliefs as adults.

As will be shown later in this article, sometimes the causal relations can be reversed, certain ideologies increasing war after a generational delay.

Science

It was shown earlier that international war has an immediate impact on the annual output of discoveries and inventions. In the previous section, however, it was seen that war can exert a long-term influence on philosophical creativity. Given that scientific creativity is partially dependent on the prevailing philosophy of a given age, the latter result implies that war might have enduring consequences for science as well. For instance, it seems reasonable to infer that scientific ideas might become less empirical and materialistic in line with similar changes in philosophy. Regrettably, no research has investigated this possibility. Even so, one empirical study has indicated a possible immediate connection between war and science in psychology. The [Peter Suedfeld \(1985\)](#) content analyzed the presidential addresses delivered by 85 Presidents of the American Psychological Association. The speeches were specifically scored for integrative complexity, a measure of how many distinct perspectives a person considers and the extent to which these perspectives are successfully integrated. Some of these presidential addresses were delivered during peacetime, whereas others were delivered during the Spanish-American War, one of the two World Wars, the Korean War, or the Vietnam War. Cognition was much more complex in those addresses given during times of peace. What makes this correlation even more interesting is that the distinguished psychologists who score high on integrative complexity tended to practice a different kind of psychology than those who score low. The former are more prone to view psychology as a human science, and thus be more humanistic or clinical in their orientation, whereas the latter are more likely to see psychology as a natural science, and therefore be more behavioristic or experimental in orientation. By implication, the presence or absence of war seems associative with qualitative differences in psychological science.

Effects of Creativity on War

It has been assumed so far that creativity is somewhat at the mercy of politics. War either lowers the amount of creativity or else modifies the nature of the creativity that does appear. Despite that assumption, sometimes researchers have found evidence for influences going in the opposite direction. These consequences operate at two levels, the aggregate and the individual.

At the aggregate level, there is some tentative evidence that certain ideologies tend to encourage the development of the militaristic ideas that lead to war ([Simonton, 1976](#)). This evidence came from a generational time-series analysis that compared the relation between prevailing philosophical beliefs at generation g and the level of international war at generation $g + 1$. When civilization becomes dominated by sceptical and materialistic ideologies, then warfare was likely to increase about 20 years later. This time-lagged relation held from the ancient Greeks to the beginning of the 20th century. Because scepticism and materialism may undermine ethical values, and even lead to a high degree of political cynicism, the youth exposed to these ideas may be more disposed to become adults who are far more willing to see war as a viable means to attain a desired end. This possibility may bring to mind the ideal leader according to *The Prince* written in 1513 by Niccolò Machiavelli: The end justifies the means.

At the individual level, it becomes useful to return to the concept of integrative complexity. As noted earlier, integrative complexity tends to decline during wartime, and it tends to be associated with the type of psychology displayed by a President of the American Psychological Association. But the variable's connections with both war and creativity are even more complicated than so far discussed. To start with, integrative complexity is positively correlated with creative problem solving. Creative people are able to look at a problem from multiple perspectives and, when necessary, discover a solution that integrates those alternative points of view. Thus, Albert Einstein examined a problem in physics from the standpoint of both Newtonian mechanics and Maxwellian equations, saw the contradiction between the two, and resolved the conflict by deriving his special theory of relativity. By the same token, high integrative complexity is associated with effective leadership, especially in the area of decision making and problem solving. For instance, the more successful US presidents score higher in integrative complexity than do the less successful. In the case of war, integrative complexity is involved in two ways.

First, research has shown that international crises are more likely to result in international war when the political leaders facing crisis score low in integrative complexity (e.g., [Suedfeld and Tetlock, 1977](#)). If the goal is to resolve the conflict, then leaders must be able to examine the issues from multiple perspectives, and then find a satisfactory integration of those perspectives. The various parties to the crisis can then identify a resolution that allows the tensions to be reduced peacefully. If the leaders score low in integrative complexity, they can only see the crisis from one point of view (their own), and reconciliation becomes impossible. War then becomes the only answer. In a sense, when a crisis results in war, it is a sign that the world's leaders failed to exhibit sufficient creativity.

Second, once war breaks out, military leadership becomes more critical than political leadership. To a very large extent, the nations with the superior commanders will have an edge over their opponents in the conflict. Research indicates that those military leaders who score highest in integrative complexity are most likely to emerge victorious in battle ([Suedfeld et al., 1986](#)). To be effective, a commander must be able to view the military situation not only from his point of view but also from that of the enemy commander. By inspecting the situation from all possible perspectives, the commander can determine the most probable consequence of a given tactical decision. In short, the leader can "second guess" his opponent. Of course, integrative complexity is probably an asset with respect to strategy, and not just tactics. Hence, it enhances the national capacity to win the war, not just the battles making up the war. In short, military success demands a certain amount of creativity.

These two points taken together point to an ironic conclusion: It may take some amount of creativity to avoid war, and also a certain amount of creativity to win a war once it has begun.

Conclusion

Creativity is an enormously important phenomenon. Modern culture is largely the accumulation of creative acts since the beginning of civilization. War is also a tremendously significant phenomenon. Few political events affect so many people so dramatically, and often permanently. The history of humanity is very much a narrative of its major wars, battles, and conquests. Putting these two obvious facts together might lead to the conclusion that the relation between creativity and war would be a frequent subject of research. Yet that is far from the case. Direct empirical studies of their association are actually quite rare. To be sure, this article has reviewed a rich inventory of empirical results. However, close examination of the literature shows that the diverse findings are scattered and disconnected. Too often one investigator will approach the topic in ignorance of past research already published on the subject. As a consequence, frequently researchers end up duplicating results rather than building on the prior results of their predecessors.

Another liability has to do the lack of a strong theoretical foundation for almost all published inquiries. The typical investigation tends to be exploratory, war constituting just one of numerous situational factors thrown into a set of independent variables. Complicating the problem all the more, investigators do not always define war in the same way, thereby obtaining divergent results. Furthermore, as mentioned earlier, researchers have often employed rather diverse methodological approaches, such as contrary units of analyses. Such contrasts can also affect the outcomes.

In light of these unfortunate limitations in the research, it is hoped that future investigators will adopt a more systematic approach to this crucial question. In particular, subsequent investigations should adopt a stronger theoretical framework that more firmly guides the critical methodological choices. Until then, those curious about the relation between creativity and war must be contented with a heterogeneous collection of piecemeal observations.

Introduction

This entry will provide an overview of the research techniques used to study eminent creative writers as well as the results of the research. These writers were deemed eminent through their body of work rather than any single publication. Their creativity was evident in the exceptional quality of their work which clearly differentiated them from their peers.

Writers have been studied using a variety of techniques including studies of biographies, interviews and assessment of writers, case studies, evaluations of the writing process, psychobiographies and the systems approach. The results of this research will be summarized regarding early family history, education, mental illness, suicide and lifespan. Research related to the creative process includes motivation and personality factors as well as work habits. Finally, writing used in institutionalized settings as an aid for recovery will be discussed.

Research Techniques

Studies of Biographies

Researchers seek generalizations about eminent writers by compiling statistical data using biographies. They compare this data with information about other creative achievers and the general population, looking for any significant differences. Conclusions from these types of studies may apply to writers as a group, but do not indicate the characteristics of any individual writer.

[☆] *Change History:* 2019. Changed title from Writing and Creativity to Writers. Changed abstract, added Introduction, updated research and cut section regarding non-eminent writers and healing.

This article is an update of S.R. Pritzker, Writing and Creativity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 525–532.

Interviews and Assessments of Writers

Researchers interview eminent writers about their work and in some cases give them psychological evaluations and tests. The majority of these studies evaluate the characteristics and mental health of writers. Other researchers conduct semi-structured interviews focusing on a writer's background, career path, motivation, work habits, internal processes, and personal life. When multiple interviews are conducted, connections that indicate similarities and differences between the subjects are usually offered. Researchers have also used archival interviews in books, magazines, and newspapers to analyze prominent writers.

Case Studies

Researchers prepare case studies about individual writers by studying their life and work. The results presented in this entry will not emphasize individual case studies since they are usually complex and vary widely depending on the training, methodology, and perspective of the author. Study of collaborative creative writing is just beginning. A combination of interviewing, observation, and evaluation of changes in the work offer insights into the decision-making process as well as the personal dynamics and leadership factors which may encourage or discourage creativity. Case studies may provide valuable insights but the results can't be generalized.

The Writing Process

The mechanics of the writing process including preparation, writing and rewriting have been examined from different angles. Genetic criticism defined two ways to study the writing process – program writing and process writing (See [Alamargot and Lebrave, 2010](#)). Program writing focuses on an individual creative writer's actual work from preliminary sketches through completion looking for a pattern. Process writing looks at the inspiration and then the revisions. Many authors alternate between structuring and working in a more flexible format.

Neuroscientific studies examining the writing process in real time are relatively rare but one study indicated significant differences in cerebral activity between professionally trained and inexperienced writers ([Kessler et al., 2014](#)).

The Psychobiography

Freud expressed admiration for creative writers who he said were far in advance of everyday people, because they draw on sources which have not yet opened in science. Freud wrote about the life of DaVinci which served as the prototype for the psychobiography, a format in which key psychological elements in an author's life, which theoretically influenced their work, are presented. Psychobiographies are almost always made without the subject's participation. Critics of this methodology complain there is a great deal of unproven speculation involved, as analyses are not based on experiments or independent evidence. The psychoanalytic method may reduce life to psychological processes, ignoring social, economic, or political forces. More recent researchers in creativity, such as Howard Gardner, concluded that Freud's characterizations apply to noncreative as well as creative individuals and thus do not distinguish the effective artist or scientist from the banal one. Others believe that though Freud's work was not scientifically accurate, his method might provide an imaginative look into the mystery of creativity.

The literature includes many articles by psychological practitioners who analyzed the content of a writer's work including themes and specific characters in relation to a specific personal characteristic of the author, such as psychopathology, addiction, disease, or wish fulfillment. A few psychoanalysts and psychologists, most notably Albert Rothenberg, worked with writer-clients who allowed them to write about their creative process using aspects of their therapy.

The Systems Approach

The evolving systems approach [see [EVOLVING SYSTEMS APPROACH](#)] examines the creative person's life in five contexts, including: total body of work, the milieu in which they worked, their family and personal life, and the sociohistorical period in which they lived. This approach has been used in studying writers by examining their creative process based on different drafts of their work and their own recollections.

Results of the Research

Early Family History

Large scale biographical studies consistently indicate that successful writers came from more turbulent family backgrounds and suffered more emotional instability when they were children. [Goertzel et al. \(1978\)](#) studied the lives of 717 eminent personalities who had two or more biographies written about them since 1962. The Goertzels compared 92 literary figures with other eminent personalities who lived in the 20th century. They found writers were:

1. More likely to be only children (26% vs. 17% overall).
2. Tended to be voracious readers (77% vs. 48%).
3. Disliked school (52% vs. 33%).
4. Came from homes described as very unhappy (67% vs. 44%).
5. Had more alcoholic parents (one or both) (11% vs. 7%).

Jane Piirto (2002) reviewed the lives of 160 writers using survey questionnaires, essays, published interviews, and reference books. She found family trauma was a theme including alcoholism, parental suicide, weak or absent fathers, being orphaned, poverty, physical and sexual abuse, divorce, and mental illness. A few writers had placid childhoods but they represented a small percentage. Numerous writers and researchers have commented that writers may often find a way in their work to create a new world for themselves.

Arnold Ludwig (1995) examined the lives of 1004 eminent people who had a biography reviewed in *The New York Times Book Review* between 1960 and 1990. Included in the total were 180 fiction writers, 64 nonfiction writers, and 53 poets. He found that writers were more likely to have fathers, mothers, and siblings with identifiable pathological problems. In a separate study, Ludwig found that significantly more women writers came from families with mothers or fathers with psychopathology and that more of these writers were physically or sexually abused as children.

Kay Jamison (1993) described the genealogies of a number of writers who had close bi-polar relatives which included Robert Burns, Charles Dickens, Ralph Waldo Emerson, Ernest Hemingway, Henry and William James, William Faulkner, and F. Scott Fitzgerald. This may have been a creative advantage since research conducted by Ruth Richards and Dennis Kinney indicated that an individual with a close relative who is bipolar is more likely to be creative. (See Bipolar Mood Disorders).

Education

Not surprisingly, the majority of children who became writers were voracious readers who escaped into the world of books and in some cases movies. Freud wrote about the relationship between childhood fantasy and writing: "Might we not say that every child at play behaves like a creative writer, in that he creates a world of his own, or, rather, rearranges the things of his world in a new way which pleases him?" (1908: 131–132).

Exceptional curiosity was a common trait along with an early interest in writing. Young writers such as Eugene Ionesco, Sylvia Plath, and Pearl Buck displayed promise and received encouragement from teachers for their writing skills. However others such as Academy Award winning screenwriters William Goldman and Tom Schulman did not display any particular talent for writing until later in life. Many creative writers were bored or just felt they did not fit in. High school dropouts include famous writers such as Herman Melville, Mark Twain, Ring Lardner, Will Rogers, and Noel Coward.

However the romantic notion of the dropout writer who lives in poverty until discovered is changing as the path for many successful writers, especially novelists, includes an undergraduate and graduate school degree, often from top-flight schools that may allow them to teach as their writing career evolves. Programs such as the Iowa Writers Workshop and UC Irvine and top film schools such as USC and UCLA are training successful writers.

Mental Illness

Writers, along with other creative artists, have been subject to the speculation that genius and madness are linked. This association can be traced back to Plato's colorful description of poets' 'divine madness' as well as Aristotle's claim that all creative people were touched with melancholia. Biographical studies support the notion that fiction writers and poets had much higher rates of psychopathology than other creative professions and the general population.

For example, Arnold Ludwig (1995) reported that 28% of his total sample of writers had a mental disorder in their lifetime including a striking 87% of poets, 77% of fiction writers, and 72% of nonfiction writers. Women writers may be even more at risk. Ludwig (1994) interviewed and compared 59 female writers matched with a control group. He found female writers had higher rates of depression (59% vs. 9%), alcoholism (20% vs. 5%), drug abuse (17% vs. 5%), panic disorder (22% vs. 2%), generalized anxiety (14% vs. 5%), and eating disorders (12% vs. apparently none). Women writers, like men, suffered more bipolar illness and depression, but they also had had more problems with alcohol, were more suicidal, and had a lower life expectancy than other eminent professionals.

Andreason conducted structured interviews with 30 faculty members at the Iowa workshop over a period of 15 years. She performed a psychiatric diagnosis of both writers and their relatives, comparing them with a matched control group. She concluded that 24 of the 30 writers (80%) suffered from an affective disorder compared to nine (30%) of the control sample. She diagnosed 13 writers with a bipolar disorder and 11 with a major depressive disorder. In fact, two writers committed suicide while the study was taking place. Using the family history method, she also diagnosed the writers as having many more first-degree relatives with affective disorders and creative ability. Andreason recognized the limitations of her study, including the fact that she was cognizant of the writers and the controls. Also, writers might have more awareness of affective illness both in themselves and in their relatives. She also commented that the degree of illness diagnosed might be exaggerated by the broad definition of bipolar illness in the DSM. Andreason was the sole interviewer and this particular group of writers may have turned to teaching because of depression.

Kay Jamison (1993) interviewed 47 British prize-winning writers and artists with a mean age of 53.2 years, asking them if they had been treated for mental illness. She discovered that 38% had been treated for affective illness at some point, 23.4% had taken antidepressants, and 6.4% had been diagnosed as manic-depressive (all poets). She compared this with 'normal lifetime rates' of 5% for depression and 1% for manic-depression.

The most comprehensive face to face study of professional writers was analyzed by Frank Barron (1961), who, with other psychologists, interviewed and psychologically tested 30 professional writers nominated by the faculty of the University of California at Berkeley. Also included in this study were 26 'successful and productive' student writers and nonwriters. Barron tested for the presence of psychopathology by administering the Minnesota Multiphasic Personality Inventory. He found the most eminent writers scored high on scales measuring schizoid, depressive, hysterical, and psychopathic tendencies and in terms of femininity of interest pattern. However, these writers also registered higher scores on ego strength, so Barron concluded that while they suffered psychological turmoil, they also possessed more resources to deal with it. He felt this conclusion was reinforced by their social behavior since they presented themselves as clearly effective people with pride and distinctiveness while sometimes showing pain, protest, distance, and withdrawal, as well as being very emotional. Barron's study warrants replication with a contemporary group of writers because his conclusions might vary with subjects who lived in a different time frame.

There is also evidence that more successful writers who win Nobel Prizes and Pulitzer Prizes may be more likely to have mental illness. James Kaufman found similar results in two historiometric studies of 986 20th century writers and 889 writers who lived from 1600–2000. He concluded that: "In both studies, both types of prize-winners were more likely to suffer from mental illness than nonwinners. In addition, Nobel Prize winners were more likely to suffer from alcoholism ... and experience a personal tragedy" (2000–2001: 305). A partial list of writers thought to have serious mental illness problems are listed in Table 1. An interesting point in looking at this incredible group of talented writers is that they had illustrious careers despite having to deal with mental illness.

Ludwig suggested that writers demonstrate more psychopathology because writing and poetry rely on a 'personal vision' which is based on an internal subjective experience as opposed to science where more stability may be required to do work that has 'predictability, replicability, reliability, and testability.' The arts tolerate eccentric and irrational behavior much more readily than other professions. In fact, the creative writer's uniqueness is his or her stock in trade, and it takes a strong, independent personality to go one's own way. The characteristics that support this kind of abnormality are similar to the traits that characterize psychotic behavior. For example, James Joyce's unique thought processes influenced the language in his work which became his creative hallmark.

There is also the distinct possibility that the characteristics of mental illness can be a detriment or benefit to creativity, depending on the individual case. For example, creative writers and poets may be far more sensitive to their emotions. Freud felt writers use fantasy to satisfy these needs. This anticipates other researchers who concluded the difference that composes what has been called the thin line between genius and madness is control. This point of view acknowledges that creative writers may at times exhibit traits of mental illness, but argues they are essentially healthy because they can make critical judgments about their thoughts and work that would be impossible if they were truly pathological. Other researchers take the opposite position that psychotic thinking is an essential ingredient in creativity.

A third possibility accepts both psychopathology and creativity as ingredients which may vary along a continuum. At times creativity and schizophrenia may be inextricably linked together in varying degrees. Examples include the poet Holderlin, who was diagnosed as schizophrenic; Strindberg, who had a schizoaffective disorder; and writers who displayed a schizoid or schizothymic temperament, including Baudelaire, Kafka, and Beckett. It may be the schizoid or schizotypal propensities and world view which gave these writers' creative contribution its uniqueness.

Hypomanic traits have been cited as a positive force giving some writers energy, concentration, and confidence which enhanced their work. Depression inspired a small percentage of writers to work harder, perhaps attempting to escape their pain. Other writers such as Edgar Allan Poe used their dark moods as a source for some of their best work.

However, most writers with mental illness paid a heavy price in both their personal and their professional lives. Most reports by psychiatrists, psychologists, and writers indicate that being in the throes of mental illness is not a good place to work. Richard Berlin argued that: "Severe depression interferes with motivation, energy, drive realistic self-assessment, and pleasure" (2008: 4). Sylvia Plath said "When you are insane, you are busy being insane all the time ... When I was crazy, that's all I was" (Flaherty as cited in Berlin, 2008: 4). Ezra Pound, Virginia Woolf and Sylvia Plath spent parts of their lives in mental institutions. Depression and manic-depression hampered the ability of many eminent writers, including Joseph Conrad, Leo Tolstoy, John Ruskin, and Ernest Hemingway.

Summing up, there are impressive indications that eminent writers as a group suffer more problems than other eminent creators or the general population. Despite the robustness of the statistics, they must be considered cautiously. Diagnoses have often been made posthumously using loose and inconsistent diagnostic criteria. In many cases the validity of a diagnosis of mental illness, alcoholism, or suicide cannot be verified. In addition, solid statistical evidence of the extent of mental illness, alcoholism, and suicide in the general population is still far from precise. Finally, it is possible writers with dramatic lives and early deaths are more likely to become eminent and have biographies written about them.

Table 1 Writers thought to have mental illness

James Barrie (playwright/fiction)
Charles Baudelaire (poetry/nonfiction)
Honore de Balzac (fiction)
William Blake (poetry/fiction/nonfiction)
Elizabeth Barrett Browning (poetry)
Robert Browning (poetry/playwright)
Truman Capote (fiction/nonfiction/playwright)
Samuel Taylor Coleridge (poetry/nonfiction/playwright)
Joseph Conrad (fiction/playwright/nonfiction)
Hart Crane (poetry/playwright/nonfiction)
Charles Dickens (fiction/playwright/nonfiction)
F. Scott Fitzgerald (fiction/nonfiction)
Ian Fleming (fiction)
Robert Frost (poetry)
Nikolai Gogol (fiction/playwright)
Graham Greene (fiction/nonfiction/screenplays/playwright)
Ernest Hemingway (fiction/nonfiction)
Franz Kafka (fiction/nonfiction)
Jack London (fiction)
James Joyce (fiction)
Robert Lowell (poetry/playwright)
Guy du Maupassant (fiction/nonfiction/poetry)
John Stuart Mill (nonfiction)
Frank O'Connor (fiction/nonfiction/playwright)
Sylvia Plath (poetry/fiction)
Edgar Allan Poe (poetry/fiction/playwright)
Ezra Pound (poetry/nonfiction)
Arthur Rimbaud (poetry)
William Saroyan (fiction)
Friedrich Schiller (poetry/drama/nonfiction)
Arthur Schopenhauer (nonfiction)
Delmore Schwartz (poetry/fiction/nonfiction)
Anne Sexton (poetry/fiction/nonfiction)
Percy Bysshe Shelley (poetry/fiction/nonfiction/playwright)
Christopher Smart (poetry/nonfiction/librettos)
August Strindberg (playwright/fiction/poetry)
Jonathan Swift (fiction/nonfiction/poetry)
Torquato Tasso (poetry/playwright/nonfiction)
Alfred Tennyson (poetry/playwright)
Leo Tolstoy (fiction/nonfiction/playwright)
Virginia Woolf (fiction/nonfiction)

Note: Many authors are classified as having mental illness automatically if they demonstrated heavy use of alcohol or drugs.
Sources: Ludwig, Magill, Prentky, Simonton, and others.

Suicide

Individuals who have problems with traumatic childhood loss, mental illness, alcoholism, and drug abuse are more likely to commit suicide, so it is not surprising the suicide rate among writers is higher than average. Difficulty with their writing is a factor contributing to writers' suicides. A partial list of writers who are believed to have committed suicide is in [Table 2](#).

In [Ludwig's \(1995\)](#) study, eminent people in general were more likely to commit suicide (4.4%) than the general population, which had an estimated rate of 1.0% to 1.4%. However, 20% of the poets were considered suicides. Fiction writers had an average rate of suicides while nonfiction writers were below average. Ludwig proposed that emotional problems often interfered with creative productivity, but actually improved performance for 16% of eminent creative people by increasing productivity, overcoming writing blocks, and generating new ideas or better performances. The Goertzel found that 11% of writers committed suicide compared to 5% of their total sample.

Poets are more at risk than other groups and female poets represent the highest percentage of writers who commit suicide. [Kaufman and Baer \(2002\)](#) pointed out that female poets are introspective and the expressive nature and style of their poetry does not provide the health benefits of other kinds of writing. They cited other salient reasons including the implicit expectations of illness by the gatekeepers who evaluate poetry, the higher evidence of mental illness in female poets and the fact that poets tend to peak at an earlier age when bipolar illness and other mood disorders are more likely to strike. (See Poetry)

Table 2 Some writers thought to have committed suicide

Ryunosuke Akutagawa (fiction)
John Berryman (poetry/nonfiction/fiction)
Truman Capote (fiction/nonfiction/playwright)
Thomas Chatterton (poetry/playwright)
Hart Crane (poetry/playwright/nonfiction)
Maxim Gorky (fiction)
Spalding Gray (screenwriter/performer)
Tom Heggen (fiction/playwright)
Ernest Hemingway (nonfiction/fiction)

Substance Abuse

Alcoholism has been a problem for many accomplished writers, including Nobel prize-winning authors Sinclair Lewis, Eugene O'Neill, and William Faulkner. The generation of American expatriate writers in post-First World War Paris that included Ernest Hemingway and F. Scott Fitzgerald glamorized and romanticized drinking, making it a more sophisticated and respectable behavior. A partial list of alcoholic writers includes James Agee, Charles Bukowski, Truman Capote, Raymond Chandler, John Cheever, Dashiell Hammet, O. Henry, James Joyce, Jack Kerouac, Norman Mailer, Dorothy Parker, Edgar Allen Poe, John Steinbeck, Robert Louis Stevenson, William Styron, Dylan Thomas, Tennessee Williams, and Thomas Wolfe. Writers who used their drinking experiences for major works include Eugene O'Neill (*The Iceman Cometh*), William Burroughs (*Naked Lunch*), and Malcolm Lowry (*Under the Volcano*). Jack London wrote an alcoholic memoir (*John Barleycorn: Alcoholic Memoirs*) and Charles Bukowski's semi-autobiographical fiction and poetry were filled with his alcoholic experiences.

Albert Rothenberg reviewed biographical and autobiographical data of writers known for their use of alcohol. He found very few did their actual writing or their thinking about writing, while under the influence of alcohol. In Ludwig's study of the biographies of 34 well known heavy-drinking writers, artists, and composer/performers, he found that alcohol negatively affected the work of 75%, especially as the drinking continued. Long-term drinking has physiological effects which directly hinder the concentration required of creative individuals. However, Ludwig believed that drinking actually benefited 9% of the subjects. Writers such as Hemingway, O. Henry, Raymond Chandler, and John O'Hara claimed that drinking *improved* the quality of their writing. Many writers recognized they could not write well while they were drinking. F. Scott Fitzgerald and Ring Lardner said they went on the wagon when they worked.

Koski-Jannes (1985) reviewed 60 interviews with prominent Finnish writers who started writing between the 1920s and 1950s. Only 32 writers commented on their use of alcohol while they wrote since this was not a primary question in the interviews. Writers who used alcohol occasionally saw it as an aid in getting started or a stimulus when they were tired. Duplicating results of studies in England and the United States, poets reported more alcohol use than other types of writers. The most heavy use for all writers occurred between writing projects.

Immediately after a project was finished, writers reported they felt "empty, depressed and dissatisfied with themselves." They considered going out and drinking as a way to loosen up and relax, make social contacts with other writers, and generate new ideas. Writers also said they used alcohol to dissociate themselves from common concerns, and to facilitate the writing process. Koski-Jannes suggested that among the reasons writers use alcohol frequently are that the job is insecure, highly valued but poorly paid (at least in Finland), and the profession is subject to conflicting expectation from the reading public, critics and the writer her or herself (lose publicity pressures). As actual work it is unstable, lonely and at times emotionally highly demanding. Because of the marginality of this profession the identity of the writer is continually at stake (1985: 131).

These comments sum up the hazards of the job mentioned by a number of researchers. However, it does not explain why some writers respond to these pressures by drinking heavily while other writers drink in moderation or abstain. A few researchers have

attempted to determine if alcohol facilitates creative writing under laboratory conditions. There were indications that alcohol significantly increased the number of words produced, which confirms anecdotal accounts of writers who found alcohol an aid in writing. However, these studies did not examine professional writers, so any determination of the quality of thinking under actual working conditions remains unknown.

Often the term 'depression' is mentioned when it comes to writers who drink, which indicates that it may be used as a form of self-medication. If, in fact, more writers tend to be alcoholics than the general population, it is still not clear if the job makes writers depressed or depressed people are more likely to choose writing as a profession. Since most alcoholic writers were drinking before they started writing, perhaps professional writing was attractive because it allowed the individual the freedom to continue drinking. It is also possible that writing, like alcohol, serves as a way to escape negative feelings.

A questionnaire given to writers on this topic indicated that writers experience positive emotions significantly more often than negative emotions when writing. Furthermore, during the actual writing process, positive emotions tended to intensify, whereas negative emotions resisted change. Ludwig's analysis indicated that poets and fiction writers trail only musicians and theatrical performers when it comes to drug use and abuse. Coleridge allegedly wrote about the palace of Kublai Khan while on opium; Keats tried the drug and described his experience. Elizabeth Barret Browning, Louisa May Alcott, and Jean Cocteau used opium. Aldous Huxley made no secret of his fondness for mescaline, which he wrote about in *The Doors of Perception*. Phillip K. Dick was addicted to amphetamines. Stephen King wrote in 2000 about being hooked on alcohol, cocaine, and prescription medicines.

It's impossible to accurately measure the level of drug use because, aside from the question of legality, some writers might be afraid their reputations would suffer if they publicly admitted they used drugs. As times change, writers' use of alcohol and drugs may change. Recent studies challenge the popular notion that creatively successful individuals lead excessive life styles. A survey of 22 writers, 27 artists, 12 musicians, and 25 controls about use of cocaine, marijuana, alcohol, etc. found no significant difference in the use of most substances between groups. However, a high rate of heavy use (23%), a small sample, and an even smaller control group preclude any definitive conclusions.

Life Span

Researchers concluded the stresses caused by being a professional writer result in a measurably lower life expectancy. A comparison of the age of death of 160 writers with that of 80 members of nine other creative occupations found that writers died at an average age of 61.7 years, which was 8.3 years less than composers and painters. Several hypotheses have been put forward to explain the cause of writers dying at an earlier age:

1. The theory that poets produce their major works at a younger age so they could die at a younger age and still be considered eminent in their field.
2. The differential-resources hypotheses, which suggests the lower financial rewards and standard of living in the literary arts results in a shorter life expectancy.
3. The stimulation-deprivation explanation which posits the meager financial rewards and sensory stimulation found in writing leads to risk-taking behavior elsewhere.

A study by [Vincent Cassandro \(1998\)](#) found creative writers living an average of 62 years, which was three to seven years less than contemporaries in other disciplines. Scientists and inventors lived the longest. Cassandro concluded evidence supported the first two hypotheses, but not the third. He also made the logical link between a writer's psychopathology and a lower life expectancy. This is exemplified by the fact that poets are definitely more at risk than fiction and nonfiction writers. In 2003, [Kaufman \(2003\)](#) found this higher risk for poets cut across cultures in a study that looked at 2000 American, Chinese, Turkish, and Eastern European writers. This is not surprising in view of the fact that poets suffer more mental illness, substance abuse problems and suicide.

Cassandro's study offered significant evidence that the more writers diversified, the longer they lived. However, the sample was of subjects born no later than 1800 and thus might not generalize to the 21st century. Similarly, the findings might not apply to less eminent creative people or for writers in different fields. In 2009, [Steven Pritzker and David McGarva \(2010\)](#) found that Academy Award winning screenwriters lived to an average age of 72 although it has slipped below 70 since the 1970s. More in-depth research verifying the actual economic status of the creators studied, the actual cause of death, and the interaction of psychopathology upon these variables could help build knowledge in this area.

Writers Creative Process

Motivation and Personality

Why do writers write? It has been proposed that mental disturbances contribute to a state of 'psychological unease' which generates creative tension that is relieved by constant work, and that creators who do not have emotional problems are able to internally generate this unease. Others have theorized that writing may satisfy a biological drive, a search for meaning, or a means to fame and fortune. Barron theorized that writers are constantly creating a universe of meaning. This need to find meaning in life may be based on childhoods in which writers felt isolated and unhappy. This theory could explain why so many writers find the act of writing difficult. Creating a world that reveals lasting truths is bound to be frustrating as the writer searches for the right words.

However, despite all the pressures and frustrations, many writers have found great satisfaction in their work. For some, writing provides an escape from the pressures of life, offering a place where he or she is in control. Positive aspects frequently mentioned include the pleasure in discovering more about themselves and making new intellectual and emotional connections, feeling they have a real purpose, communicating with others and sharing their reactions when they find something which represents some underlying 'truth' about life, and the enjoyment of working with words. Some individuals found a long-sought sense of identity when they became writers.

Two motivations to write which have not been explored in depth are fame and fortune. Research in experimental settings has indicated that the relationship between intrinsic motivation and extrinsic motivation varies according to circumstances. It is probable that in the real world fantasies of celebrity and wealth helped some writers keep working through the lean times. Economic necessity motivated some writers. Dostoyevsky produced some of his best work when he needed money.

Many novelists and playwrights in the twentieth Century took lucrative offers from movie studios. Some including Fitzgerald and Faulkner felt that they 'sold out' to Hollywood where they had no control over their work. Usually they wrote bitterly about the experience.

Fame, once achieved, has been a part of the career fabric for many authors who enjoyed the attention. Ernest Hemingway's macho image helped sell his work while giving him ego gratification. However, fame also creates tremendous pressure. Expectations can become so high that writers become blocked. Writing became especially competitive in the 1920s when writing a great novel was not enough – it had to be a best seller.

Today's authors are expected to sell themselves on social media, tv and radio interviews and appear at book signings so they can generate enough publicity to become a 'name brand.' The alcohol and drug problems many writers experience may be exacerbated by the drive for success, prestige, fame, and money, and the burden put on the creative self.

Work Habits

Creative writing may be sparked in many ways (e.g., a glimpse of a person or imagining a scene) and inevitably encompasses autobiographical elements. Once the subject is chosen, some prolific writers such as Stephan King can produce work with incredible speed. Isaac Asimov reported he would write at the 90 words a minute he could type, and stated he wrote most nonfiction books in 70 hours. However, many writers struggle finding the form which fulfills their vision.

Writers' work habits are as individual and idiosyncratic as their work. Some professional writers discipline themselves by treating writing as a nine to five job. Others may give themselves a daily quota of words or pages to fill. There are writers who like to isolate themselves while others enjoy working in cafes. Some write a specific number of pages every day while others procrastinate until they are faced with a deadline and then put in marathon hours.

Most writing decisions offer a number of choices, so often writers develop different drafts of stories and scenes, learning as they rewrite what works for them and what must be changed. During this evolutionary process their original perceptions may radically shift – a minor character may grow into a central figure, or the theme of a story may go in a completely different direction.

Thus the creative process in writing is usually not linear, but rather a series of steps that are repeated over and over as refinements are made. Many writers will look for feedback from one or more trusted sources while the work is in progress. Some writers may complete hundreds of pages and decide the idea does not work at all. The most constructive work is done in a state of total concentration which almost seems effortless at the time, referred to as 'flow.' The author must remain open to the message whispered by the unconscious, while at the same time maintaining critical judgment.

Writer's Block

A common complaint among both amateur and professional writers is the inability to work known as writer's block. This experience is intimately connected to the uncertainty and tension inherent in facing a blank page every day. Factors contributing to writer's block are self-doubt, perfectionism, procrastination, unrealistic expectations, and fear of failure. Some strategies suggested for countering blocks include writing anything (even about being blocked), setting up a regular time and place to write, isolating oneself from distractions, stopping writing when there is some momentum left so the work can be continued the following day, going to another project for a while, and using positive self-talk. The fact that even blocked writers may eventually produce important work is exemplified by Karl Marx, who spent 18 years writing the first volume of *Das Kapital*.

Collaborative Writing

The act of writing is usually an internal process so it has been difficult to make independent observations of elements that encourage or discourage creativity. Research about collaborative writing in television script writing, indicates that specific elements encourage creativity, including the willingness to take risks and providing a safe atmosphere where members of the group build upon each other's' ideas while they are free to argue (Pritzker, 1998). Negatives include unresolved emotional conflict between the writer and supervisors, differences in communication styles, settling quickly on a predictable story, and the tendency of executives to demand massive rewrites generating fear of change and fatigue.

Creative Writing in Institutions

Creative writing is used as a tool to help prisoners and patients dealing with mental illness. Cognitive researchers concluded that creative writing takes tremendous effort and requires a great deal of attention; thus for some troubled people it helps center the thinking process and provides insight into problems. William Styron and Art Buchwald wrote about their deep depression as a catharsis and with the hope the public would understand more about the debilitating nature of their illness. Political prisoners such as Thomas Paine, John Bunyan, and Daniel Defoe used their time in jail to write books that furthered their own cause. Prisoners committed for other crimes who wrote notable works while in jail include O. Henry, William Penn, Marco Polo, Oscar Wilde, Eldredge Cleaver, and Malcolm X. The Marquis de Sade completed the circuit since he began his writing career in prison and continued it in a mental institution.

Conclusions

Work on writing and creativity has consistently indicated that many writers suffer problems with psychopathology, alcoholism, and drug abuse. The next step is to go beyond the interesting and logical theories proposed for this connection and develop verifiable causal explanations.

Information on the life expectancy of writers needs further investigation. If writing inherently contains occupational hazards, then therapists and creative writing teachers can develop a proactive stance to help some of their clients understand and cope with the stress of the job and deal with their personal demons.

Much of the research has concentrated on eminent writers. Learning more about professional writers who are more 'ordinary' can widen the knowledge base and possibly lead to training which can encourage creativity.

While a great deal of attention has been paid to dysfunctional writers, the healthy writer (if one exists) is barely represented in the literature. It might prove worthwhile to look closely at the lives of writers with less dramatic histories since they may serve as positive models other writers may emulate.

Introduction

In Shakespeare's *Twelfth Night* a character utters the famous lines "Some are born great, some achieve greatness, and others have greatness thrust upon them." The first option would seem to apply to royalty and aristocrats, and the second to the great geniuses who make history [see Genius and Greatness]. The third possibility suggests that sometimes greatness is not a matter of being the right person but rather can be attributed to being at the right place at the right time. Even creators as outstanding as René Descartes, William Shakespeare, Leonardo da Vinci, and Ludwig van Beethoven are nothing more than products of larger sociocultural circumstances beyond their control. In a sense, geniuses are mere epiphenomena – effects rather than true causal agents. That is, geniuses are pawns of the Zeitgeist, a German word that literally means "time spirit," or "spirit of the times." The word "Zeit" has the same origins as the English root "tide" still seen in such words as eventide, Christmastide, and Shrovetide. And the German word "Geist" has the same source as the English "ghost," which came from the Old English word for breadth or spirit. The term Zeitgeist is closely linked with Ortgeist, another German word that signifies "spirit of the place." In practice, the two terms can be used interchangeably. The near equivalence ensues from the fact that the "spirit" is invariably confined to a particular time and place. For example, when we speak of the Age of Pericles we are simultaneously talking about a particular place (Athens) at a specific time (about 445–429 BCE) – the Athenian Golden Age. There was no Periclean Age in Rome, and even less in Africa, Asia, and the Americas. Hence, throughout this article Zeitgeist will be used in the inclusive sense to encompass the Ortgeist as well.

As the preceding example illustrates, the Zeitgeist is often associated with eponyms – names of persons that became labels for eras or periods in history. Other examples include the Elizabethan Age in England or the Age of Louis XIV in France. Even so, sometimes the Zeitgeist is identified by more impersonal names, such as Renaissance Italy or the British Industrial Revolution. The latter usage is more consistent with the tenor of the Zeitgeist theory of history. The expression Victorian Age seems to imply that the British Queen Victoria had something to do with the making of the age. Yet Zeitgeist advocates, such as Leo Tolstoy in his *War and Peace*, are emphatic that eponyms have no causal significance. On the contrary, the Queen was the pawn rather than agent of her age. Her sole contribution was to live long enough to provide an all-encompassing label for a whole period in history.

[☆] *Change History:* May 2019. Dean Simonton updated the text throughout the article.

This article is an update of D.K. Simonton, Zeitgeist, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 533–538.

In its extreme form, Zeitgeist theory becomes equivalent to sociocultural determinism and reductionism. All individual behaviors, including creativity, are determined by social and cultural variables. As such, the individual is reduced to a set of norms, roles, and other factors that exist outside the person, and prior to the person. However, it is possible to acknowledge the impact of the Zeitgeist without adopting such an extremist stance. The Zeitgeist then provides a set of variables that join psychological and biological factors in the making of the creative genius.

To understand better how the Zeitgeist affects creativity, we must first recognize that the Zeitgeist assumes two forms: the internal and the external.

Internal Zeitgeist

At the level of everyday creative behavior, creativity can often be generic. Thus, a person who writes an imaginative American haiku might also produce a creative collage. In contrast, high-level creativity tends to be much more domain specific. It is as unlikely that T. S. Elliot could have painted *Guernica* as it is improbable that Pablo Picasso could have penned "The Waste Land." Accordingly, to some extent the Zeitgeist must also be domain specific. The Zeitgeist associated with Newtonian or "Classical" physics will have a far greater influence on the creativity of physicists than it will on the creativity of sculptors. Likewise, the Zeitgeist connected with Socialist Realism had a bigger impact on the arts than on mathematics.

One illustration of this domain-specific contingency is seen in the phenomenon of role-model availability. It has been long observed that creative genius is not randomly distributed across time and place. Instead, geniuses tend to congregate into temporally and geographically restricted clusters – the best of which are often called "Golden Ages." Moreover, these clusters take time to emerge and time to dissipate. Typically, a given civilization might begin with a few progenitor or precursor geniuses, and in successive generations the creativity attains a climax, after which activity trails off in a series of epigones or inferior successors. Hence, although the Golden Age of Greek philosophy is clearly defined by the apex represented by Socrates, Plato, and Aristotle, this peak was preceded by pre-Socratic thinkers and succeeded by post-Aristotelian thinkers of lesser merit – such as Democritus and Theophrastus, respectively.

Detailed generational time-series analyses [see War] have identified the basis for this clustering (Simonton and Ting, 2010). Each generation of creators tends to build upon the work of the previous generation. As Plato builds upon Socrates, so does Aristotle build upon Plato. It is extremely rare for a creator to appear *de novo*, sans predecessors, and whenever that happens the creativity tends to be inferior to what occurs during the climax. In a nutshell, creative development is contingent on the availability of role models during the creator's childhood and adolescence, when the individual is acquiring creative potential. And, obviously, that role-model availability is most effective if its domain specific. Albert Einstein's creative potential is going to be fostered more by senior physicists than by older architects. When Newton famously said that he saw farther than the rest by standing on the shoulders of giants, he certainly meant figures like Kepler and Galileo.

Unfortunately, once the Golden Age attains the acme, subsequent generations tend to exhibit a progressive decline. The reasons for this decadence are complex, and probably in part domain specific. Alfred Kroeber (1944), the cultural anthropologist, attributed the decline to "pattern exhaustion." After everything has been said within the constraints of a given cultural milieu, or Zeitgeist, there is no place to go next but down. Once painting has culminated in perfect photographic realism, then where can painters go next? They either must scramble to paint ever more exotic objects or they must find some alternative stylistic goal. Another disabling influence may be imitation. Too many potential creative geniuses of the post-climax generations may be tempted to imitate the masters of the Golden Age rather than risk developing their own unique voice. And ultimately such imitation may be antithetical to genius, as argued by the philosopher Immanuel Kant. At the end of World War II the Dutch minor painter Han van Meegeren was revealed to have painted imitation Vermeers that art experts had actually certified as authentic. But rather than being hailed as an artistic genius he was condemned as a mere forger of fakes. It is one thing to create one's own distinctive style from scratch and quite another to ape the style of others.

Whatever the details, role-model availability exemplifies one way that the Zeitgeist operates to influence creativity in every generation and in every creative domain. In part, the Zeitgeist in any give period consists of the inventory of recent creative achievements that can inspire subsequent creativity. Below we turn to more specific processes that are confined to particular domains. We first look at the sciences, and then turn to the arts.

Scientific Creativity

Thomas Kuhn's, 1970 *The Structure of Scientific Revolutions* presented a highly influential internalist theory of scientific discovery. The theory applies to paradigmatic disciplines in which practitioners exhibit a high theoretical and methodological consensus. An example would be physics which in the 17th and 18th centuries was largely governed by the Newtonian or "classical" paradigm. Scientists operating within a paradigm are engaged in "normal" science, a puzzle-solving enterprise that aspires to extend the paradigm's explanatory scope and precision. However, over time "anomalies" begin to accumulate. These are results that do not fit within the accepted paradigm. On occasion, these anomalous findings can be assimilated. For example, Newtonian celestial mechanics managed to explain a perturbation in the orbit of the planet Uranus by predicting the existence of a new planet. When that planet, Neptune, was observed, it became a triumphal confirmation of the paradigm. Other times the anomalies cannot be easily assimilated without introducing post hoc alternations that undermine faith in the paradigm. For instance, an anomaly in

the orbit of Mercury resisted all attempts at a Newtonian explanation (including the prediction of an unknown planet). If enough of these anomalies accumulate the discipline may enter a “crisis” state that can only be resolved by the introduction of a new paradigm [See Paradigm Shifts]. These paradigm shifts are promoted by practitioners of “revolutionary” science. An example was Albert Einstein’s introduction of relativity theory in the early 20th century. And the cycle continues. The key feature of this process is that the Zeitgeist is defined by the discipline (viz. the paradigm) rather than being determined by sociocultural factors outside the discipline, such as war [see War].

Interestingly, normal scientists can be psychologically distinguished from revolutionary scientists. To illustrate, the latter are more prone to be laterborns (Sulloway, 2014) and to exhibit higher rates and intensities of mental illness (Ko and Kim, 2008). So the paradigmatic Zeitgeist has psychological as well as disciplinary consequences.

Artistic Creativity

Like Kuhn, Colin Martindale (1990) was fascinated with disciplinary change, but in his case the focus was on stylistic change in the arts, especially in literature. Just as the paradigmatic sciences show paradigm shifts, so do the arts display stylistic shifts. A Romantic poet does not write the same kind of poetry as a Neo-Classical poet. To explain these changes, Martindale proposed an evolutionary theory. The theory begins by assuming that all creators are operating with a given set of aesthetic conventions that define a particular style. However, creative individuals are also under pressure to maintain the “arousal potential” of their products. This impetus means that they have to generate ever more novel and surprising works within the given style. To attain this end, creators have to increasingly rely on “primary process” imagery (or primordial thinking). Yet after a few generations this cognitive regression goes so far that the stylistic constraints begin to break down. The style then becomes exhausted in a manner similar to Kroeber’s concept of pattern exhaustion. The only salvation is to introduce a new style. Because the style itself is novel, arousal potential can be maintained without much regression into primary process. And the cycle then repeats.

Martindale (1990) has conducted a large number of empirical investigations that provide support for his evolutionary theory. Most notably he has used computerized content analyses to show that over the history of any given literary tradition both primary process imagery and stylistic change tend to exhibit inverse oscillations. When a new style is introduced primary process declines. At the same time, Martindale has shown that these stylistic changes are internal to a given art form. That is, such changes are affected very little by external events.

External Zeitgeist

The German philosopher Georg Wilhelm Friedrich Hegel argued that history was driven by a dialectic process involving pure ideas. A given ideational thesis would yield an antithesis which in its turn would produce a synthesis – and the latter would be a new thesis for the continuation of the cycle. Political, social, and economic systems were nothing more than manifestations of that intellectual history. In contrast, Karl Marx famously “turned Hegel on his head” by arguing that the dialectic was materialistic rather than idealistic. In particular, the economic system, as defined by the means of production, underwent a dialectic process that drove history through the successive stages of slavery, feudalism, capitalism, and finally communism. In the Marxian view, the world of ideas – including both artistic and scientific creativity – was but the external consequence of the resulting economic conditions. Feudal art or science would have to be different than capitalist art or science because they reflected contrary materialistic circumstances. Needless to say, this reflectionist or externalist perspective is antithetical to the internalist positions discussed previously. It leads to a sociocultural determinism in which both paradigms and styles are epiphenomenal rather than causal. When artists in a communist state turn to “Socialist Realism” it is not because the previous style had exhausted itself but rather because the new style better complies with the new economic milieu.

Although the extreme position is probably overstated, it remains true that creativity is not completely immune from the external Zeitgeist. The latter impact is evident in empirical research on how political, economic, and sociocultural circumstances affect both the quantitative and qualitative aspects of creativity observed at a particular point in time.

Quantitative Aspects

The impact of the external Zeitgeist on the quantity of creativity can be assessed two main ways.

On the one hand, we can use generational time-series analysis to count the number of creators active in each time period, where the latter is most often taken as a 20-year interval (Simonton, 1984). Specific political, social, economic, and cultural events or conditions can then be assessed in the same intervals. The relation between these two time series then provides information about the connection between the two measures. However, often the association between the two series is lagged rather than simultaneous. More precisely, the number of creators in generation g might be a function of the external Zeitgeist in generation $g - 1$. This lagged function would imply that the magnitude of creativity is contingent on the developmental experiences that future creators have in childhood and adolescence. As an illustration, for many domains of creativity the number of creators at generation g is a negative function of the level of political anarchy at generation $g - 1$, where the latter is gauged by political assassinations, military revolts, palace coups d’état, and the like (Simonton, 1975). Another feature of the political Zeitgeist that may have a lagged effect is political fragmentation (i.e., the number of independent or sovereign states into which a given civilization is divided). Growing up

under such conditions may enhance creative development, possibly via increased bilingualism and multiculturalism (but see Refs. [Simonton and Ting, 2010](#)). In the same vein, civilizations tend to become more creative a generation or two after they have been exposed to influences from alien civilizations or cultures ([Simonton, 1997, 2018](#)). In a nutshell, the aggregate level of creativity is prone to increase after an influx of sociocultural and linguistic heterogeneity.

On the other hand, we can use a smaller unit of time, such as a single year, to tabulate the number of creative products in a given temporal interval. This approach is clearly more refined. Shorter units of analysis allows for the possibility that the external Zeitgeist might have more finely-tuned effects. If certain extrinsic conditions can fluctuate rapidly from one year to the next, then their consequences will be overlooked when using larger aggregates. A prime example is the impact of war [see War]. Although war has no effect on the number of creators counted into 20-year periods, this dramatic condition does have a repercussion at the level of yearly tabulations. When war is followed by peace creators seem to make up for lost time, and thus create the works that were set aside during the military conflict. So the adverse impact is obliterated when the analysis expands from years to generations.

All in all, it is apparent that the quantitative implications of the external Zeitgeist are substantial. They can determine both the number of creators that appear in a given generation and the number of creative products that appear in a given year.

Qualitative Aspects

The qualitative impact of the Zeitgeist is perhaps even more interesting than the quantitative. During a specific period in history, the number of creators in Chinese civilization might equal the number of creators in European civilization, and yet the products generated by these two sets of creators might be radically different in qualitative characteristics. In the case of painting, for example, Chinese painters might be creating highly idealistic landscapes that exist only in the artist's mind while European painters are creating highly realistic portraits of actual people.

Fortunately, some empirical research does indeed show that external conditions affect qualitative features of creative products. To illustrate, consider the following set of findings: (a) compositions in the classical repertoire exhibit distinct stylistic aspects depending on whether they were composed during peacetime or wartime conditions ([Simonton, 1986](#)); (b) specific features of Greek ceramic paintings reflect the degree to which economic and political power was concentrated in a small proportion of people ([Dressler and Robbins, 1975](#)); and (c) the thematic material presented in plays corresponds to a noticeable degree with concurrent political events ([Simonton, 2004](#)). These effects are all contemporaneous, whereas other external influences require a substantial delay. An especially interesting lagged effect is the polarizing effect of civil disturbances ([Simonton, 1976](#)). One generation after a region has seen an increase in nationalistic revolts or political rebellions there tends to be a divergence in the positions advocated by notable philosophers. That is, thinkers who grew up under such circumstances have a higher likelihood of becoming proponents of diametrically opposed viewpoints. For instance, there will appear both extreme materialists and extreme idealists, extreme empiricists and extreme rationalists, and so forth.

To be sure, the correspondences are far from perfect. Many creators will be sufficiently individualistic that their work will not accurately reflect the external Zeitgeist. Even so, enough creators in any given generation conform enough that their products taken as a whole will represent their times.

Mixed Zeitgeist

Naturally, the foregoing represented extreme positions. The Zeitgeist is not exclusively external or internal. Rather, the two guises of the Zeitgeist operate together. Creativity in most domains is the joint function of both the internal and external Zeitgeist. That conclusion can be illustrated using both artistic and scientific creativity.

Artistic Creativity

Creativity in the arts is contingent on both types of Zeitgeist. This contingency is apparent in the empirical research on the thematic material in the compositions that make up the classical repertoire. On the one hand, it is clear that themes or melodies undergo stylistic changes, just as in literary creativity. The music of the Baroque period is identifiably different from the music of the Classical or Romanic periods. Moreover, the evidence suggests that these stylistic shifts are partly driven by the same kind of processes that [Martindale \(1990\)](#) discusses in his evolutionary theory. For example, because of the constant pressure on composers to be original, their melodies tend to become more novel, surprising, and unpredictable over the course of their careers. This longitudinal trend then induces a historical trend: Melodic originality tends to increase over time ([Kozbelt and Meredith, 2010](#)). On the other hand, the research also shows that the nature of the melodic material also depends on the larger sociocultural conditions. For instance, melodies become more unpredictable and variable when a composition is created under wartime circumstances – particularly if the composer is active near the war zone ([Cerulo, 1984](#)). There is even an Ortgeist effect. Provincial composers who were born and raised far from the music centers of their day tend to create less strikingly original themes relative to cosmopolitan composers who emerged from one of the centers of music activity ([Simonton, 1986](#)).

The foregoing illustration concerns qualitative effects operating on single creative products. Yet the internal and external Zeitgeist can also exert joint quantitative effects on individual creators. This twofold influence is apparent in research on the Japanese literary

tradition (Simonton, 1992). One peculiarity of this literature is the conspicuous presence of female writers, particularly during the Golden Age represented by the Heian period. As a case in point, Murasaki Shikibu, who is credited with writing the world's first true novel, has something of the status of William Shakespeare in English literature. Even so, it is also clear that the appearance of outstanding female literary creators fluctuated throughout Japan's history, and in some periods they would disappear altogether. It turns out that both internal and external factors are involved. In the first instance, female literary greats are most likely to emerge in those generations that feature male literary greats. Stated differently, only when Japanese culture favored literature as a form of creative expression will women have a high probability of making a contribution. In contrast, the appearance of female writers is uniquely discouraged by such extraneous conditions as Confucianist ideology. Because Confucianism promotes a hierarchical system that places women in an inferior position, it harms female creativity but not male creativity. Indeed, the dominance of Confucian ideas inhibits female achievements in other domains besides literature.

Scientific Creativity

From time to time two or more scientists will make the same discovery independently of each other. Well-known examples include the calculus by Newton and Leibniz, the conservation of energy by Mayer, Helmholtz, and Joule, the theory of evolution by natural selection by Darwin and Wallace, and the plague bacillus by Yersin and Kitasato. Likewise, it sometimes happens that two or more inventors will independently create the same invention. Instances include the ophthalmoscope by Babbage, Helmholtz, and Anagnostakis, photography by Daguerre and Talbot, and incandescent lamp carbon filament by Swan and Edison. Such events have been termed multiple discoveries or inventions, or just plain multiples [see Multiple Discovery]. What renders these occasions especially dramatic is that sometimes the multiples are virtually simultaneous. In effect, Alexander Bell and Elisha Gray showed up at the US Patent Office with their respective inventions of the telephone on the exact same day! Furthermore, many more than two rival claimants may be involved. The dynamo may have had as many as nine independent inventors. Nor are these multiples rare. Examples run into the hundreds.

This phenomenon has often been taken as prime evidence for sociocultural determinism, the strongest form of Zeitgeist theory (Lamb and Easton, 1984). Although research shows that this inference is unjustified – multiples are largely chance events – it remains true that they illustrate the influence of the Zeitgeist. The Zeitgeist provides the necessary but not sufficient conditions for a given discovery or invention. Calculus presupposes an analytic geometry, which in its turn depends on the prior advent of algebra, the latter being contingent on the previous existence of arithmetic. In this case, this sequence of dependencies illustrates the internal Zeitgeist within the discipline of mathematics. Yet on occasion the internal Zeitgeist will be joined by the external Zeitgeist, creating a mixed effect. A particularly dramatic example is the atomic bomb. The internal Zeitgeist in nuclear physics had already demonstrated the theoretical possibility of such a weapon. But it took the external Zeitgeist, in the form of World War II, for physicists to receive the tremendous resources required to convert this possibility into a reality. Although the atomic bomb was not a multiple, it might have become so had not the defeat of Germany terminated its own program.

Individual Versus Society

Too often the Zeitgeist is evoked to minimize the importance of the creative individual, even the creative genius. This derogation is especially commonplace in many discussions of multiples. If both Newton and Leibniz came up with the calculus, then the calculus must have been “in the air” just ripe for the picking. However, this implication does not follow from the evidence. Nor do the other findings mentioned earlier in this article serve to dethrone the individual creator. The creative person remains for three main reasons.

First, two individuals can be born in the same place and time – identical Ortgeist and Zeitgeist – but still exhibit greatly differing degrees of creativity. One might become a universally hailed genius while the other becomes an obscure also-ran. Conversely, two persons of comparable achievements might be born in very different times and places. Consider the four scientists credited with discovering the Mendelian laws of genetics: Mendel, born 1822 in Heinzendorf bei Odrau, Austria (now the Czech Republic); Hugo de Vries, born 1848 in Haarlem, Netherlands; Carl Correns, born 1864 in Munich, Germany; and Erich von Tschermak-Seysenegg, born 1871 in Vienna, Austria.

Second, even when exact contemporaries and compatriots exhibit equal magnitudes of creativity, that creativity may appear in totally distinct domains of achievement. Where one becomes a Nobel laureate in physics, the other might become a laureate in literature. Any large metropolitan area in any given year will give birth to dozens if not hundreds of creative individuals who make their respective contributions to radically different domains.

Third, the level and the type of creativity are both determined by numerous variables that are inherent in the singular creator. Indeed, these non-Zeitgeist influences explain the previous two observations. The most obvious influence is genetic inheritance, which will affect both the type and magnitude of creativity. In addition, different creators will grow up under distinct family backgrounds. In fact, even if two creative individuals came from the same household, they might differ because of their birth order. As an example, the Tolman family in West Newton, Massachusetts, had two sons born 5 years apart. The oldest, Richard, became a famous mathematical physicist, whereas the youngest, Edward, became a famous psychologist. Beyond the family there are various other developmental influences, such as education, mentors and role models, friends and colleagues, work environments, etc. This huge inventory of developmental experiences serves to individualize each creator. Consequently, each creator becomes something more than just a pliable pawn of the Zeitgeist.

Glossary

Beginner's mind The many possibilities regarding meditation in the mind of a beginning mediator.

Enlightenment A final blessed state marked by the absence of desire or suffering.

Koan A paradoxical question that cannot be answered using ordinary logic.

Mushin The state of 'no mind' or 'no ego' in which true emptiness is achieved.

Nirvana An advanced state of enlightenment in which desire, frustration, and ignorance are dissipated so absolute silence and stillness reign.

Samadhi The state in which consciousness is stopped and the individual is no longer aware of time, space, and causation.

Satori The moment of enlightenment when one sees into one's own nature.

Zazen Zen sitting meditation.

Zen A Japanese sect of Mahayana Buddhism that aims at enlightenment by direct intuition through meditation.

Brief History of Zen Buddhism

Prince Gautama was born near the border of Nepal and India in approximately the 6th century BC. His wealthy father gave him every luxury and kept him protected within the palace walls. When the prince finally left his sheltered life, he was very upset when he encountered sickness, old age, and death. He met a holy man who seemed happy despite the problems that surrounded him, so the prince decided he would seek his own liberation. He became a holy man, wandering the country without finding peace. Finally he vowed to sit on a straw mat under a bodhi tree until he found an answer. He sat there for six days. On the morning of the seventh day, he awakened to the morning star and became enlightened. Prince Gautama became known as The Buddha.

Tathagata developed the Four Noble Truths, which emphasized that life's suffering was engendered by selfish craving that could be overcome through following the eightfold path of right understanding, purpose, speech, conduct, livelihood, effort, alertness, and concentration. The detachment of a solitary life led to liberation. The ultimate goal was achieving Nirvana, which represented a state of undisturbed peace.

[☆] *Change History*: 2019. Revised abstract, updated research and added small edits. Added key words, new references and a website.

This article is an update of S.R. Pritzker, Zen, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 539–543.

The founder of Zen Buddhism was The Bodhidharma who was the 28th patriarch of Indian Buddhism. He arrived in China about AD 520. The Bodhidharma meditated facing a wall for nine years before becoming a teacher. His teaching was based on the principles of Mahayana Buddhism, which emphasized helping others and concrete experience. His disciples continued teaching in China.

Zen became recognized as a separate branch of Buddhism about AD 700 during the time of the patriarch Huineng. Huineng stressed the concept of emptiness, which minimized the importance of the individual ego in a world where everything and everybody are connected and constantly changing.

Zen Tenets

This section reviews basic tenets of Buddhism including suspicion of language, meditation, the use of koans and enlightenment. The Bodhidharma called for 'no dependence on words and letters' but 'direct pointing to the real person, seeing into one's nature and attainment of Buddhahood.' Buddha stated that all humans are inherently enlightened; however, there is a need to practice in order to remove the obstacles to experiencing satori. Satori is reached through the study of koans, meditation, and living a purposeful life. 'Chop wood, drink water' – concentrate on what is necessary at this moment. It takes most people a great deal of training to calm what is called in India 'monkey mind,' the constant chatter of thoughts, for even a few moments. Zazen is a form of meditation in which concentration on breathing and calming the mind helps the practitioner lose awareness of the body. The goal is to reach a state where time, space, and causation, as the framework of consciousness, drop away.

Koans are a unique method of teaching. The student is assigned a koan – for example, 'What is the meaning of Mu?' The individual repeats the koan over and over during meditation until suddenly its truth is revealed.

There are rare times when enlightenment happens very quickly but most people reaching enlightenment can be a long, challenging path. Philip Kapleau (1965) suggested that the three essential qualities necessary for enlightenment include (1) strong faith, (2) a strong doubt based on the imperfect state of the individual and the world compared to the idealistic image, and (3) strong determination to dispel this doubt with the whole force of one's energy and will.

Enlightened individuals are encouraged to participate in life. D. T. Suzuki stated that "the object of Zen training consists in making us realize that Zen is our daily experience and that it is not something put in from the outside." The enlightened individual interacts with everybody in a different way because the desire for ego gratification and material things no longer dominate the individual's thinking. Success and failure, happiness and unhappiness all become an accepted part of life.

Zen and Creativity in China and Japan

By AD 800 Zen was widely practiced in China. Zen's influence on culture was relatively minor. It contributed to Chinese philosophy in the Sung dynasty and a form of 13th century asymmetrical painting called *one corner* that was eventually exported to Japan. This inspired the *thrifty brush* style of Japanese painting that reflected the simplicity of Zen experience. Zen gardens and calligraphy also originated in China, but it was in Japan where Zen had the most impact on culture. Zen monasteries became the primary source of learning and art for the upper classes in Japan. Creativity was inherent in the teaching practiced by the Zen masters who used improvisational methods specifically tailored to the individual student.

The model of discipline and concentration required in Zen influenced other aspects of life. Training was often done by a master teacher similar to a roshi or Zen teacher. The idea of reaching mushin, a state of 'no mind,' penetrated the arts in Japan and stimulated creativity in many areas. Mushin represents the highest state of consciousness with no thoughts or judgments clouding the mind. Students practiced calligraphy, painting, or archery until the routine requirements – the moving of the pen or brush or the firing of the bow – could be accomplished automatically without thought. This training took many years because conscious control was not surrendered easily. Students without self-consciousness could completely absorb themselves in the moment, allowing intuition rather than intellect to control their process. When the mind was clear with no duality in the way, true human nature could take over and the artist knew where the brush was supposed to go. Zen influenced the following professions:

Architecture and Design

Many great Zen temples began as imperial palaces and castles. They are noteworthy because they reflect and respect the unique beauty of the gardens that surround them.

The Japanese tea room, which originated in the 15th century, is an excellent example of how Zen deeply influenced many aspects of Japanese culture. The tea ceremony is a ritual designed as a diversion from the everyday world. Each tea room is built specifically for the individual tea master.

The ceremony begins with a walk through a garden where stepping stones form an asymmetrical path. The walk through a tea garden is intended to foster recollection and inner peace. The tea room's construction is deliberately delicate, consisting of bamboo supports and thatched roofs. The interior is strikingly simple with a fire pit, tatami mats, and a hanging scroll or some other object of art. Tea ceramics are a Japanese art form. Each item is carefully chosen to be part of a group. After the special tea is brewed and drank, the tea master and guests may discuss each implement or the beauty of nature. Ordinary business matters are left outside in this

special world. The simplicity of tearoom decor has influenced the design of functional things, including kitchen implements, floor mats, textiles, and common bowls and cups.

Calligraphy

Calligraphy originated in China in the 3rd century AD. The ink (sumi) was mixed using an inkstand to grind an ink block made of lampblack and glue. Sometimes poetry was created spontaneously, which contributed to the development of haiku.

The first Zen calligrapher was Huang Ting-chien (1045–1105) who became enlightened and recognized this changed the quality of his writing. Dogen Kigen (1200–1253), a legendary Zen master, founded the Soto sect. He was a highly skilled calligrapher who emphasized the importance of meditation.

Art

Ashikaga monochrome ink painting began as a natural extension of calligraphy. The black ink can be mixed in various shades that suggest the perception of color. As stated by T. Hoover, the purpose of Zen painting is to penetrate beyond the perceptions of the rational mind, to show nature's essence. The artist paints the enlightenment of the moment, and therefore has no time to labor over each stroke. Absolute concentration is crucial because no retouching can be done. The artist never pauses to evaluate his work. The ink flows in a dramatic flurry of strokes producing a sense of rhythm, movement, form, and the artist's vision of life's inner music.

This type of painting began in the Sung dynasty in China as a rebellion against conventional art similar to the abstract expressionist movement. Ch'an monks threw ink and rubbed it in by hand or using their hair. Three types of schools emerged: Zenkiga emphasized Zen parables, insight, and practice. Chin'z specialized in portraits of well-known Zen teachers.

A third school focused on landscape painting with a very specific set of rules including which items were usually present (mountains, trees, rocks, etc.). Each painting was divided into three tiers that illustrated the scene from different perspectives. These landscapes pioneered concepts that became important in other Zen art including the symbolic use of empty space and emphasis on rocks and trees, which eventually became significant metaphors.

Japanese monks who traveled in China brought Zen painting home in the 13th century. Sesshu Toyo (1414–81) reinvented the form so that it reflected Zen precepts in its veneration of nature's beauty. He inspired a number of other artists who worked for the next 150 years.

Gardening

Zen gardens were also inspired by Chinese models created during the Sung dynasty. The use of rocks, trees, sand, and water were replications of Ashikaga ink landscapes. The idea of depicting a garden as a three-dimensional painting inspired the development of perspective and abstraction approximately the same time as Ucello (1397–1495) was doing similar work with painting in Italy.

The Zen garden was designed, like a painting, for viewing with the hope the emotional reaction of the viewer would inspire greater awareness. Excellent examples from the 13th and 14th centuries are in Kyoto. War and poverty in the 15th century inspired the creation of stark stone gardens called *kare sansu*. These monochromatic gardens were specifically designed for meditation. They anticipated several art techniques by centuries including the abstract expressionist 'symbolic arrangement of mass and space.'

Haiku

Haiku is a tightly structured poetry format that requires the use of exactly 17 syllables. The poems are written in time to the seasons and often encompass themes about nature. Created in the 14th century, haiku was popularized by the Zen monk Basho (1643–94). Haikus represent Zen thinking in absolute absorption in the moment, offering a direct clear unmistakable experience without reference to anything else.

With every gust of wind,
The butterfly changes its place
On the willow

The best haikus are those which arise from the tension between the rigidity of the form and the depth of the poetic feeling.

Other Arts

The No drama, developed in the 13th century, used masks, dances and poetry to explore emotional experience. However, because there is no story and very little movement, most untrained Westerners have difficulty appreciating the plays. Like other Zen arts, the purpose is to inspire a profound emotional response. The Japanese puppet theater was also impacted by Zen.

Zen was used to train the samurai in swordsmanship and archery. The Zen archer practiced breathing until it was second nature and the arrow could be released without thought. Intense concentration allowed Zen archers to attain phenomenal accuracy. A Zen mind-set helped warriors overcome fear and respond automatically and unconsciously with deadly accuracy during battles. In 1281, the samurai defeated Kubla Khan's army of more than 100 000 men. Zen also influenced the creation and training in martial arts such as kung fu, aikido, and judo.

Psychotherapy

Dr Shoma Morita developed Morita therapy in Japan in 1917. Noda (2009) noted that: "Drawing from Zen Buddhism, Morita therapy essentially helps people accept their destiny. In addition, the way people and traditional healers coexist reveals uniquely Japanese ambiguity and wisdom for accepting life as it is" (p. 167). The original method was focused on behavior change in clients with a variety of anxieties.

Naikan (which means inner looking in Japanese) takes place at a number of centers around Japan where patients stay for a week which is similar to the structure of Buddhist retreats. Ryback et al. (2001) stated:

"The Naikan-sha (client) is invited to meditate from 6 in the morning until 9 in the evening (meal and bathroom breaks excepted) in a comfortably seated position focusing on problematic interactions with significant others, taken in life-long chronological order – parents, siblings, spouse, and so on" (p.133).

Specific themes focusing on relationships are selected and then short face-to-face meetings occur every hour or two. This format of brief highly focused meetings is what a Zen roshi (teacher) might do. A recent study indicated that a combination of Morita and Naikan therapy was effective in helping patients with general anxiety.

Hakoniwa is a therapy used in Japan which resembles Sandplay in the West. Zen gardens are designed to invoke both a sense of beauty and peaceful spirituality. During the session a miniature Zen garden with various figurines and objects is available. Clients build gardens that "may describe their internal world, and together with other methods, may begin to formulate a narrative of themselves" (Merlino, 2010, p. 1).

Renku is group therapy that directly uses the creative process in a format reminiscent of haiku. Participants each write a short verse: "The challenge of each individual is to render the previous stanza as deeply understood as if one were in the person of the author of that stanza, with both conscious as well as unconscious spheres of knowing" (Ryback et al., 2001, p. 132). The goal is to increase empathy and create a sense of group harmony.

Zen and Creativity in the West

After the Second World War II, teachers from Japan moved to the United States and Europe establishing Zen centers in major cities and mountain retreats.

Beat Zen Writing and Music

Beat Zen was embraced in the 1950s by some writers and musicians who felt they were rebelling against American conformity. Alan Ginsberg's poems reached a wide audience, while Jack Kerouac wrote popular semiautobiographical novels such as *The Dharma Bums*. Drugs, especially marijuana, were identified with beat Zen enthusiasts. Alan Watts felt Kerouac wrongly extended 'anything goes' at the existential level to his writing and personal life. He argued that the social responsibility inherent in Zen Buddhism was forgotten in Beat Zen.

John Cage developed a form of 'music' that used multiple tape recorders and wrote a piano recital where the pianist did not play a note, but a page turner still turned the pages. Meditation music labeled Zen has become so popular there are channels available on the streaming services.

Books about Zen and using Zen multiplied with training advice and application for a number of fields including education, writing, career planning, guitar, and even stand-up comedy. Peter Matthiessen, a Zen practitioner for many years wrote about his search for inner peace in *The Snow Leopard*, (1978) which won the National Book Award. As vegetarian diets increased in popularity, some Zen cookbooks cracked the marketplace.

Physiology

Meditation, mental exercises (koans), and skill training have been sources of interest for researchers in neurology and biology. Alpha biofeedback training may have originated with electroencephalogram (EEG) monitoring of Zen and Yoga practitioners

who claimed that meditation may create a unique form of consciousness. Researchers found that zazen, when practiced by Monks, created slower breathing patterns and more muscle relaxation.

In 2009, Alberto Chiesa summarized key points after reviewing the literature including the finding that increased theta activity in advanced meditators helped relax various regions of the brain as well as reducing stress and lowering blood pressure. He added that: "Zen meditation practice could protect from cognitive decline usually associated with age and enhance antioxidant activity" (p. 585).

There may be similarities between meditation and the flow state in terms of total absorption. A small study of musicians indicated that even a brief period of meditating may help reduce performance anxiety. However, there is still a great deal of research needed to understand the potential for positive interaction between Zen meditation and the arts.

Psychology

Zen has been advocated by some psychologists as a valuable tool that can complement traditional therapy. Modern interpretations of this include relaxation exercises, hypnosis, biofeedback, and openness to experience.

Carl Jung admired Zen, but felt the states achieved sometimes had delusional elements. Like most Western psychologists, Jung believed in the concept of the self, which could never really know the collective unconscious. This viewpoint contrasted sharply with Buddhist practice, in which the experience of satori awakened and absorbed the unknown self into a world beyond human consciousness.

Some theorists criticized the use of Zen in therapy, suggesting that Zen's fixation on enlightenment could trigger psychological problems. Another criticism was that Morita therapy was inappropriate for patients in the West because of its cultural dependence.

Other psychologists proposed that Zen could help reduce the ego, expand consciousness, and promote self-integration. The argument was made that the sudden enlightenment and gradual training in Zen practice were comparable with 'insight' and 'working through' in psychology. The concept of personal growth inherent in Zen is a cornerstone of psychotherapy, especially notable in the work of Abraham Maslow and Carl Rogers. The psychotherapist was compared to a Zen martial arts teacher in terms of developing specific teaching techniques and strategies for each client. Albert Ellis suggested that Zen could be integrated with rational-emotive therapy.

Morita therapy, Naiken, and Hakoniwa were all adapted in the West with some success. A number of American psychologists wrote books and articles with their own recommendation for combining Zen and psychology.

Creativity Research

Investigation into creativity confirms the inherent worth of aspects of Zen training. Some researchers proposed that there is a similarity between solving koans and the creative problem-solving model of preparation, incubation, illumination, and evaluation. After preparation and incubation, a solution to a koan or a problem comes suddenly and unexpectedly. Satori is similar to the 'Aha' moment in creativity. Then the viability of the solution must be evaluated.

Research indicated creativity may be facilitated in sitting meditation by freeing perceptions. Other researchers identified a satiation effect, which resulted from focusing on a picture or words with intense concentration. Eventually previous meaning dissolved, which opened the possibility for new perspectives. Creative people described a similar fixation on a specific melody when composing or a specific object when painting.

This process appears to break down previous belief systems, inhibiting cognition in favor of perception, in the same way that a Zen student must go through deconstruction of his or her belief system before arriving at enlightenment and a true understanding of the world. It is a shift in paradigms that links creativity and Zen.

A study indicated that meditation improved cognitive flexibility which in turn positively influenced creativity (Müller et al., 2016)

The ten year rule proposed by Chase and Simon in 1978 proposed that expertise takes ten years to achieve. The slow learning mentor-student relationship practiced by Zen teachers may be more effective in the long run than some Western techniques. Flow, defined as the feeling of an almost automatic, effortless, yet highly focused state of consciousness, is similar to descriptions of Zen creativity (See Flow).

Another aspect of Zen that could have application in creativity research is based on the concept of Beginners Mind (Shoshun). Shyunryu Suzuki explained this term in relation to meditation: "In the beginners mind there are many possibilities, but in the experts there are few" (p. 2, n.d.). The concept is consistent with the openness which researchers have proven is a personality characteristic of eminent creators. This openness is part of the novice effect proposed by Robert Root-Bernstein in which an insight usually occurs within the first ten years of an individual entering a field.

Kuhn's concept of Paradigm Shifts could be considered an example of Beginner's Mind – an historian approaching science from a different angle than working scientists. The concept of Beginner's Mind has potential implications for important areas of creativity such as problem finding and discovery.

Business and Sports

Zen training and ideas about creativity worked their way into mainstream thinking in Western society. Some American companies provided training in Zen meditation and principles in the 1970s and 1980s when Japanese businesses were thriving and American companies were struggling. Writers, consultants, and teachers gave advice about creative management using Zen principles, while others stressed meditation as a way to relieve stress. A recent meta-analysis of mindfulness meditation in the workplace looked at 23 studies in the workplace. The results indicate positive improvement in mindfulness, stress, anxiety and psychological distress (Bartlett et al., 2019).

In sports, *Zen and the Art of Archery* became a widely read influential book. Phil Jackson used Zen principles to coach his teams to more NBA titles than any coach in history. Tiger Woods is a Buddhist so now *The Zen of Golf* joined *The Zen of Tennis* on the bookshelf. And let's not forget *Zen and the Art of Windsurfing*.

Conclusion

Zen has influenced both the concept and execution of many different areas involving creativity, especially in Japan. The key aspects that Zen affected include the following:

1. The training for professions, which in many ways interacted and reinforced Zen principles. Each type of training became known as a way to enlightenment. A mentor–master teacher worked with students to make routine aspects automatic and as free of ego as possible. Once the ego was minimized, the mind and body were free so creativity could become natural and spontaneous.
2. An element of deliberate incompleteness that required the audience to use their own life experience to participate in the creative process. The viewer is part of the picture. Zen art is designed to be an experience grasped as a whole, not intellectually analyzed.
3. An appreciation of asymmetry and 'happy accidents' that produced distinctive products. The term *wabi* is used to describe the nobility of simplicity and rough edges of Zen products.
4. Increasing awareness and understanding by altering perceptions and forcing the mind to stretch.
5. Emphasis on the nonverbal with only a minimum of words even in haiku and No drama.

Zen art has touched upon almost every aspect of Japanese life and its presence is still felt today. Sensitivity to nature, the awareness of beauty, and the attention to the aesthetic details in life inherent in Japanese culture are a direct legacy of Zen creativity.

In the West, Zen influenced a variety of domains with a practical bent including writing, business, sports, and psychology. Creativity research incorporated the important concept of Beginner's Mind and Mindfulness.

INDEX

Notes

Cross-reference terms in *italics> are general cross-references, or refer to subentry terms within the main entry (the main entry is not repeated to save space).*

The index is arranged in set-out style with a maximum of three levels of subheading. Major discussion of a subject is indicated by bold page numbers. Page numbers suffixed by t, f, and b refer to Tables, Figures, and Boxes respectively. *vs.* indicates a comparison.

The index entries are presented in word-by-word alphabetical sequence in which a group of letters followed by a space is filed before the same group of letters followed by a letter. For example, entries beginning 'air density' are alphabetized before 'aircraft.' Prefixes and terms in parentheses are excluded from the initial alphabetization.
